OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION

1906-1907

GENERAL OFFICERS

PRESIDENT—WILLIAM J. MAYO	Rochester, Minn.
PRESIDENT-ELECT—JOSEPH D. BRYANT	New York.
FIRST VICE-PRESIDENT—HERBERT L. BURRELL	Boston.
SECOND VICE-PRESIDENT—ANDREW C. SMITH	Portland, Ore.
THIRD VICE-PRESIDENT—D. S. FAIRCHILD	Des Moines, Iowa.
FOURTH VICE-PRESIDENT—W. S. FOSTER	Pittsburg, Pa.
GENERAL SECRETARY AND EDITOR—GEORGE H. SIMMONS	103 Dearborn Avenue, Chicago.
TREASURER—FRANK BILLINGS	Chicago.

BOARD OF TRUSTEES.

T. J. Happel, Chairman, Trenton, Tenn., 1907.
 W. W. Grant, Denver, Colo., 1907.
 Philip Marvel, Atlantic City, N. J., 1907.
 E. E. Montgomery, Vice-Chairman, Philadelphia, 1908.
 A. R. Wright, Carroll, Iowa, 1908.
 H. L. E. Johnson, Washington, D. C., 1908.
 William H. Welch, Baltimore, 1909.
 Miles F. Porter, Fort Wayne, Ind., 1909.
 M. L. Harris, Secretary, Chicago, 1909.

JUDICIAL COUNCIL.

D. C. Peyton, Jeffersonville, Ind. W. B. Russ, San Antonio, Tex.
 P. Maxwell Foshay, Chicago. W. S. Foster, Pittsburg.
 George Ben. Johnston, Richmond, Va.

COUNCIL ON MEDICAL EDUCATION.

Arthur Dean Bevan, Chicago. J. A. Witherspoon, Nashville.
 W. T. Councilman, Boston. Tenn.
 Victor C. Vaughan, Ann Arbor, Mich. Charles H. Frazier, Philadelphia.

COUNCIL ON PHARMACY AND CHEMISTRY.

C. Lewis Diehl, Louisville, Ky. S. P. Sadtler, Philadelphia.
 C. S. N. Hallberg, Chicago. J. O. Schlotterbeck, Ann Arbor.
 R. A. Hatcher, New York City. Mich.
 L. F. Kebler, Washington, D.C. G. H. Simm, Chicago.
 J. H. Long, Chicago. Torald Soll, Cleveland.
 F. G. Noy, Ann Arbor, Mich. Julius St., Chicago.
 W. A. Puckner, Chicago. M. I. Wilbert, Philadelphia.
 Reid Hunt, Washington, D. C. H. W. Wiley, Washington, D.

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, Thomas D. Coleman, Augusta, Ga.; Secretary, Joseph L. Miller, 100 State St., Chicago. Executive Committee—Alexander Lambert, New York City; Richard C. Cabot, Boston; Herbert C. Moditt, San Francisco.

OBSTETRICS AND DISEASES OF WOMEN—Chairman, J. Wesley Boyce, 1404 H St. N.W., Washington, D. C.; Vice-chairman, Edward Reynolds, 65 Marlboro St., Boston; Secretary, W. P. Manton, 32 W. Adams Ave., Detroit, Mich. Executive Committee—C. L. Bonfield, Cincinnati; Charles S. Bacon, Chicago.

SURGERY AND ANATOMY—Chairman, Arthur D. Bevan, 100 State St., Chicago; Vice-Chairman, J. G. Munford, 29 Commonwealth Ave., Boston; Secretary, Harvey W. Cushing, 3 W. Franklin St., Baltimore. Executive Committee—Charles A. Powers, Denver; Maurice H. Richardson, Boston; Robert F. Weir, New York City.

HYGIENE AND SANITARY SCIENCE—Chairman, Prince A. Morrow, 68 West 40th St., New York City; Secretary, Elmer E. Hez, Seattle, Wash. Executive Committee—G. T. Searis, Providence, R. I.; John S. Fulton, Baltimore; Denlow Lewis, Chicago.

OPHTHALMOLOGY—Chairman, G. C. Savage, Nashville, Tenn.; Vice-Chairman, A. A. Hollobell, Buffalo, N. Y.; Secretary, Albert E. Bulson, Jr., Fort Wayne, Ind. Executive Committee—Robert L. Randolph, Baltimore; C. R. Holmes, Cincinnati; L. H. Taylor, Wilkesbarre, Pa.

DISEASES OF CHILDREN—Chairman, J. Ross Snyder, Birmingham, Ala.; Secretary, A. H. Wentworth, 552 Marlboro St., Boston. Executive Committee—Charles G. Kelsey, New York City; John Lovett Morse, Boston; W. C. Hollinger, Philadelphia.

STOMATOLOGY—Chairman, M. I. Schaumburg, 1636 Walnut St., Philadelphia; Vice-Chairman, Edward W. Branigan, 2 Commonwealth Ave., Boston; Secretary, E. S. Talbot, 103 State St., Chicago; Executive Committee—G. F. Eames, Boston; Vida A. Lath, Chicago; H. P. Carlton, San Francisco.

NERVOUS AND MENTAL DISEASES—Chairman, Morton Prince, 458 Beacon St., Boston; Secretary, T. H. Welsch, 2030 Chestnut St., Philadelphia. Executive Committee—H. Pershing, Denver; J. H. McBride, Pasadena, Cal.; Whelan Sinkler, Philadelphia.

CUTANEOUS MEDICINE AND SURGERY—Chairman, R. Campbell, 100 State St., Chicago; Secretary, M. L. Heidings, 19 W. 7th St., Cincinnati. Executive Committee—John A. Ford, New York City; Henry G. Anthony, Chicago; Douglas W. Montgomery, San Francisco.

LARYNGOLOGY AND OTOTOLOGY—Chairman, S. MacCuen, 1700 Walnut St., Philadelphia; Vice-Chairman, Philip Hamm, 419 Boylston St., Boston; Secretary, W. Sohler Bryant, 57 W. 19th St., New York City. Executive Committee—John F. Barnhill, Philadelphia; Robert C. Myles, New York City; Otto T. Freer, Chicago.

PHARMACOLOGY AND THERAPEUTICS—Chairman, H. C. Wood, Jr., 3942 Walnut St., Philadelphia; Vice-Chairman, H. R. Slack, LaGrange, Ga.; Secretary, C. S. N. Hallberg, 255 Dearborn St., Chicago. Executive Committee—O. T. Osborne, New Haven, Conn.; Heinrich Stern, New York City; Thomas F. Reilly, New York City.

PATHOLOGY AND PHYSIOLOGY—Chairman, W. L. Bier, Iowa City, Iowa; Secretary, W. B. Cannon, 688 Boylston St., Boston. Executive Committee—Joseph McFarland, Philadelphia; Winfield S. Hall, Chicago; Henry A. Christian, Boston.

"The American Medical Association, though formally accepting and publishing the reports of the various Standing Committees (to which it holds itself wholly responsible for the opinions, theories or criticisms therein contained, except when otherwise decided by the Association), does not assume any responsibility for the opinions, theories or criticisms therein contained, except when otherwise decided by the Association." TRANSACTIONS, 1874

W. B. Mayo

PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION, 1906-7

SOME OF THE SECTION OFFICERS.

1.—T. H. WEISENBURG, Philadelphia. Secretary Section on Nervous and Mental Diseases. 2.—WHARTON SINKLER, Philadelphia. Chairman Section on Nervous and Mental Diseases. 3.—WALTER L. BIERING, Iowa City, Iowa. Secretary Section on Pathology and Physiology. 4.—CHARLES S. BACON, Chicago, Chairman Section on Obstetrics and Diseases of Women. 5.—LEWIS H. TAYLOR, Wilkesbarre, Pa. Chairman Section on Ophthalmology. 6.—THOMAS F. REILLY, NEW YORK CITY. Chairman Section on Pharmacology and Therapeutics.

SOME OF THE SECTION OFFICERS.

7. W. J. RITLER, Chicago. Secretary Section on Diseases of Children. 8. DENSLAW LEWIS, Chicago. Chairman
 Section on Hygiene and Sanitary Science. 9. W. SOHMER BRYANT, New York City. Secretary Section on
 Laryngology and Otology. 10. W. C. HOLLIPETER, Philadelphia. Chairman Section on
 Diseases of Children. 11. ROBERT F. WEIR, New York City. Chairman Section
 on Surgery and Anatomy.

THE DIETETIC TREATMENT OF NEPHRITIS.*

F. C. SHATTUCK, M. D.

BOSTON.

So powerless are we directly to influence the kidneys by drugs that diet becomes of prime importance in our efforts to do our best for patients suffering from disablement of these organs, which play so leading a rôle in excretion.

The principle which should guide us may be expressed in one word—rest, provided that we remember that in the living body rest is a relative term. Absolute rest, as evidenced by cessation of the output of the kidneys, means death before many days. By rest we mean here, of course, such limitation of demand as may promote either complete restoration of functional activity, or such measure of it as may be possible, together with maintenance of the same for the longest possible time and without injury to the body as a whole or to its other important constituent parts.

Acute nephritis is of all grades of intensity, varying from a trivial process, the only danger of which is lest it become chronic, to one which totally and suddenly disables the kidneys. It is probably nearly always the result of an infection in which the kidneys may bear the brunt of the poisoning or may participate in a wide-spread disturbance, perhaps early, but more often later, in the course of the disease.

For twenty-five years it was almost universally considered the best practice to give a rigid milk diet in these cases and to force water. Water, of which milk is, of course, largely composed, was regarded as the best diuretic. Milk, moreover, contains, in an easily assimilable form, every nutritious principle necessary for the maintenance of life. The idea underlying the large ingestion of water was to scour the blocked tubules. But we have learned of late years that in many cases the main trouble lies behind the tubules in the glomeruli, the incapacity of which to filter is, in the acute stage, more likely to be increased than diminished by increasing the blood mass and blood pressure.

Experience teaches us that recovery, often complete and lasting, is the rule in acute nephritis provided that a brief danger period can be tidied over. Starvation is, therefore, now considered the best dietetic treatment of acute nephritis, absolute starvation for a few days in the severe cases with very scanty or suppressed urine and edema of rapid onset and growth. In cases of less severity, the kidneys allowing the passage of water and dropsy not increasing, about a quart of milk can be given daily and the needs of the system eked out by cereals and fats in moderate amount. The phosphoric acid in

the milk which may be difficult of excretion can be precipitated in the intestine by the addition of small quantities of calcium carbonate, as suggested by von Noorden, who also acutely calls attention to the inconsistency of those who absolutely prohibit alcohol but permit koumyss and matzoon. Moderate quantities of alcohol do no harm, he believes, though he seldom uses it. The quantity of food is to be gauged by the degree of kidney disablement as measured by the amount of urine rather than by the amount of albumin, the state of nutrition of the patient and his gastrointestinal digestive power, all combined. As convalescence advances the quantity and variety of food should be increased, including proteids. Animal broths are almost the last things to be allowed, containing little of nutritive value but extractives, which are dangerous to those liable to renal intoxication.

From a practical point of view the dietetic management of acute nephritis and of acute exacerbations of the chronic forms is essentially the same. The general condition of patients suffering from the latter may not tolerate as complete or prolonged starvation as may be safe in the former.

We have learned in these latter days that our knowledge of the real pathology of nephritis is more limited than we once thought it to be and that consequently our classification of its forms is as unsatisfactory as it is tentative. The clinician who, discouraged by his frequent failure to apply the classification of the pathologist to practice, makes a classification mainly on clinical lines, does not help matters much. For our present purpose, therefore, I shall divide the chronic cases into two classes—those cases with and those without dropsy. The second class is chiefly made up of the arterio-sclerotic and other cortically atrophied kidneys in which dropsy is conspicuously absent as long as compensatory left ventricular hypertrophy is present. In cases of chronic nephritis with dropsy, especially if the dropsy is mainly of cardiac origin, limitation of liquids is important as a rule.

As far as diet alone is concerned the chief, if not the sole, difference in the treatment of dropsical and non-dropsical cases lies in the degree of limitation of liquids, including water. In some cases, and in some stage of any case, water may be excreted with difficulty by the kidneys and, if the myocardium be at all insufficient, increasing the blood mass merely increases the load of the already overburdened heart.

In the chronic cases we have, as a rule, little hope of true recovery and yet we now and then see such a case as this. A young woman who has had renal albuminuria for more than a year marries. She is cautioned with regard to pregnancy. She nevertheless becomes pregnant before long, passes through it and labor successfully, loses her albuminuria, has a second child and remains absolutely well some years later. In other cases, apparently of the so-called parenchymatous or dif-

* Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

fuse type, we note the maintenance of apparent perfect health in combination with a highly albuminous and cast-rich urine for years and years. Apart from these exceptions, however, our aim must be to enable the patient to tolerate his disease as long and as comfortably as possible. Thoughtful attention must be given to the body as a whole, and its nutrition. What do it avail a man to gain sound kidneys if he lose his life? This means careful individualization of our cases and the effort in each case to adjust the amount, quality and variety of the food to the needs of that particular case at the given time, according to the stage and intensity of the renal process, the condition of other organs and of the whole organism. The best place for printed diet lists so kindly furnished us by the manufacturers of dietetic preparations for Bright's disease, diabetes, gout and other entities, is the fireplace. The physician should be his own prescriber of food as well as of drugs.

The exercise of that form of common sense which, if the ideal be not obtainable, knows how to recognize and secure the best regimen and mode of life possible for the case in hand is no mean help.

In cases with dropsy, with a strictness largely proportional to the degree thereof, a relatively dry diet is advisable. In the cases of contracted kidney, including the "gouty kidney" of the English, I am inclined to think von Noorden right in his opinion that we have erred in the past in forcing water, even in the absence of dropsy, thereby endangering the compensatory hypertrophy of the left ventricle, on the maintenance of which life often depends more than on the kidneys, to the slow wasting of which the system has a chance to accommodate itself.

It seems to me that the main service which von Noorden has rendered is his cogent advocacy of the limitation of liquids. The pendulum had already begun to swing away from an exclusive milk diet in chronic cases, at least, before his views became common property in this country. His varied diet with a fair amount of protein is in all essentials the same as that which I have advised my patients and taught my students to follow for at least fifteen years past. I never could see anything in the ban put on red meat save an ingenious mode of limiting the amount of meat. He who eats no meat save practically the breast of chicken eats very little, and less as time goes on, so weary of it does he become. Is it not better to talk straight as well as to think straight? I have long been in the habit of allowing my chronic nephritis meat of any color they please once a day, with fish or eggs at the other meals. As to amount I believe that the best results are to be attained only by study of the special case. We have all seen cases in which nephritis has been overlooked for some reason or another and which were suffering from too much food of all kinds. But I am sure that I have seen more patients with recognized nephritis suffering from an insufficiency than an excess of proteins. Cooking should be simple. Spices and condiments may be undesirable and their prohibition involves no hardship, at all events. Green vegetables and fresh fruits in their season are almost without exception permissible, nay desirable. The more perishable fruits, such as peaches and berries, which have traveled long distances to market, are apt to be poor things for anybody. Varieties are selected with more reference to their appearance on arrival than to their digestibility or palatability. I note that von Noorden forbids celery. I do not know how things may be now, but when I studied in Germany

thirty-odd years ago the only form of celery I ever saw on the table was the root. In this country I have seen only the stalk, which, either in the raw or cooked state, I can not think detrimental to nephritis.

The red meat calls up another fad—that of the avoidance of water with meals. Its true purpose may originally have been to limit alike food and drink and thus to reduce weight. But many persons have got it into their heads that water between meals is no longer water. The interdiction of red meat and of water with meals may be an easy way for the physician to attain a certain end. But the easy way is not always the best way, and I believe that we serve our patients, humanity and ourselves better if we avoid shibboleths, even if the so doing involves trouble and time.

Many women and some men seem to have nothing better to do than to exchange confidences—if those things can be called confidences which are openly talked of in street cars or in places of public amusement—as to their ailments, their physicians and their remedies. I recall a story which I heard of the late Dr. H. J. Bigelow, the great surgeon. A woman sent for him and talked for more than half an hour without interruption from him. When she had concluded he remarked: "Well, as near as I can find out, you have sent for me to ask whether a remedy which Dr. A. prescribed for Mrs. B. for a complaint which you have not got would be good for you." This woman had the sense to refer the question to her physician. Some have not, but go ahead and take the remedy. The practice of medicine is even to-day more of a black art than it would be if physicians always thought clearly and took the trouble to explain principles broadly to their patients. Of course, our knowledge is most imperfect and we must often base our action on half or quarter truths, even on what is not the truth although we believe it to be such at the time. But let us recognize that a fraction of truth is but a fraction, and bear in mind the saying credited to the late Speaker (Tom) Reed—"People say truth is simple: half truths are simple but the whole truth is the most complicated thing on God's earth."

I have no personal experience with the restriction of salt in the diet of nephritis. The investigations of Vidal, Javal, Lemierre Kövesi, Róthe-Schultz, Strauss and others make it certainly desirable that further clinical evidence be acquired as to its value in kidney disease with dropsy. While the reports of the many observers are by no means unanimous, the evidence in favor of a low sodium chlorid allowance is sufficient to make us ask for more light. I am only too conscious of the sketchiness of my remarks on this important subject. The imperfection of our knowledge and the size of the subject render it impossible, for me at least, to qualify or to go into minute detail. Principles are more important and of chief concern to us here.

The leading ones pertaining to the dietetic treatment of nephritis may be stated somewhat as follows:

1. Such control as we may have to-day of nephritis lies in diet and mode of life rather than in drugs.

2. Such drugs as are useful are so in their effect on the general organism or on the heart rather than on the kidneys directly.

3. In all cases of nephritis our broad aim is to spare the kidneys unnecessary work, not forgetting that urinary is but one of the systems which comprise the body.

4. In acute nephritis, as well as in acute exacerbations of the chronic forms, Doctors Diet and Quiet should work together. Starvation for a few days, pre-

portional to the intensity of the process and the strength of the patient, is the keynote of the dietetic management.

5. In the chronic forms we seek to lengthen and lighten life, an aim often largely within our power of attainment. Especially in the contracted form of kidney disease many years of life, much of the happiness which comes from achievement, days and nights of comfort, may hinge on our skill in adapting sound principles to the particular case and in securing the co-operation of the patient in carrying out the same, persistently, not spasmodically. Dietary restriction should be in the main quantitative rather than qualitative. Alcohol in moderation is not necessarily a poison and may be an aid to digestion.

6. The excess of proteid, not proteid in itself, is harmful to the chronically sick kidney.

7. A varied is more likely than a monotonous diet to promote the manufacture of good blood and thus to promote good nutrition of the body in general and of the myocardium in particular.

8. The amount of albumin is in itself no guide as to the extent of dietary restrictions.

ALBUMINURIA IN NEPHRITIS AND BRIGHT'S DISEASE.*

ALFRED STENGEL, M.D.
PHILADELPHIA.

Nicholas Cotugno, in the latter part of the eighteenth century, called attention to the coagulable quality of the urine in cases of dropsy, and Richard Bright showed the relation of disease of the kidney to dropsy and albuminuria in the early part of the succeeding century. Subsequently the pathologic observations of Bright, of Rayer and of others seemed to establish the invariable association of these conditions. Pathologists of the new school of cellular pathology confirmed the relationship of albuminuria and dropsy with an inflammatory lesion of the kidney so that in the course of time "albuminuria" and "nephritis" became terms of nearly identical practical significance.

As time went on, however, some of the physiologic chemists found that transient albuminuria or cyclical albuminuria might occur without any evidence of lasting disease of the kidneys. In the ordinary course of practice, however, physicians have looked on albuminuria as significant of nephritis, unless the evidence in favor of some temporary congestive or other condition has been well nigh overwhelming. The determination of the proper relations of these conditions to one another was made more difficult by the classifications suggested by various pathologists and clinical pathologists who sought to distinguish a number of types of nephritis and laid down complicated criteria of differential diagnosis, with the result that practically every form of albuminuria might be made to fall in some artificial group. The more accurate urinary examinations and the more careful medical diagnosis of recent years, however, have established the fact that it is necessary to distinguish between nephritis in the sense of the pathologist and nephritis or Bright's disease in the clinical sense.

It must be recognized that the kidney is a highly differentiated organ subjected to exceptional irritations in its important function of excretion, and that inflam-

matory lesions in the minute pathologic sense may be extremely frequent without of necessity leaving any lasting results. Furthermore, it is obvious that nephritis does not become a condition of grave significance until the pathologic changes have attained a degree of intensity or have involved a proportion of the kidney substance sufficient to interfere with the complex functions of the organ so as to imperil the general health. The presence of slight intertubular exudation, of moderate or even extensive, if uncomplicated, degeneration of the epithelia of the tubules, or of slight alterations in the glomeruli, would not justify a positive assertion that the case was one of Bright's disease in the clinical sense. The distinction, of course, is one of degree rather than of kind, but the point at which I am aiming is to bring out the fact that an excretory organ like the kidney is excessively prone to slight and transient alterations which in all probability will undergo satisfactory resolution without permanent impairment of the integrity of the organ.

Much difference of opinion has arisen on account of this discrepancy between slight pathologic lesions and functional or clinical manifestations. In all of the cases now in mind, albuminuria, the great criterion of nephritis, is likely to be encountered, and yet the pathologic conditions are frequently neither serious at the time nor lasting and progressive in character. It is hopeless to attempt a classification based on minute differences in the pathologic findings, and for practical purposes the old clinico-pathologic classification is still the most satisfactory. According to this, two forms of Bright's disease may be recognized, the acute and chronic parenchymatous nephritis, and a third form of nephritis, somewhat different in its clinical course and effects, chronic interstitial nephritis. Individual instances of the first and second forms vary much in the actual pathologic lesions. Sometimes epithelial degeneration is paramount; at other times exudative changes are conspicuous; changes in the glomeruli are usually pronounced and hemorrhagic processes may be conspicuous. In chronic cases, fibrosis sometimes becomes nearly as extensive as in chronic interstitial nephritis. The pathologic picture, therefore, is variegated in the extreme. Contrasted with these cases and essentially distinct from them is chronic interstitial nephritis. Analogy would indicate that the acute interstitial nephritis of the pathologist, occurring in acute infections and toxemias, might go on to the development of the granular contracted kidney, but, so far as definite knowledge is concerned, it must be recognized that this is probably rarely the sequence of events and that practically chronic interstitial nephritis is usually one of the concomitants and generally a comparatively late one of arteriosclerosis.

At the present time chronic interstitial nephritis is recognized as constituting but a subsidiary part of a more general disease in the majority of cases; while, in older days, it was regarded as an independent condition. According to this later view, polyuria and albuminuria may be regarded as significant merely of a renal form, or a renal phase, of a general vascular disease.

Contrasted with these three types of permanent renal disease, there is a large number of conditions in which the kidney is temporarily involved, in which evidences of renal irritation or inflammation exist, and in which the pathologist might discover some pathologic changes, though the subsequent course is one of rapid resolution. The mere element of speedy restoration is evidently not

* Read in the section of Practice of Medicine of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

dependent so much on the extent as on the character and intensity of the renal trouble. Such cases are frequent in association with infectious febrile processes and with circulatory disturbances. It is in these cases that some of the clinical signs, especially albuminuria, of Bright's disease occur, and it is these that cause the difficulty in distinguishing between true Bright's disease in the sense of the clinician and the nephritis of the pathologist. Doubtless until some means have been devised for estimating accurately the functional capacity of the kidney, it will remain difficult for the clinician to establish positive diagnoses and prognoses in certain borderline cases, but in the meantime a close study of the general features of the cases in which albuminuria and casts are encountered, but in which lasting nephritis does not follow, will enable the clinician to avoid error in the majority of instances.

Before proceeding to further discussion let me emphasize with all earnestness that diagnosis in renal disease can not proceed from the urinary examination alone any more than can the diagnosis of cardiac disease from physical exploration alone, or that of typhoid fever solely from the examination of the serum for the reaction of agglutination. Taken in conjunction with the general symptomatology, accurate examinations of the urine are indispensable, but without the general conditions as a check urinary examination may be as misleading as would be the symptoms without the urinary findings.

It has interested me to look over the records of my private cases to determine how frequently albuminuria occurs in the run of cases in general office practice. These figures have the advantage that they represent the results of a single examiner's work and from one method of examination (heat and nitric acid). In the great majority of cases several examinations were made at different times, an added advantage considering the frequency with which albuminuria occurs as a temporary condition.

Among 581 cases there were 51 cases of undoubted clinical nephritis or Bright's disease, exclusive of chronic interstitial nephritis. In all of these there was constant and more or less uniform albuminuria.

In 74 cases of arteriosclerosis there was more or less inconstant albuminuria, without casts in 16 and with casts in 58. A number of these cases might properly have been classed as chronic interstitial nephritis. In all of these there was constant and more or less uniform albuminuria. In practically all it may be assumed that a certain degree of chronic interstitial nephritis existed, though other manifestations of arteriosclerosis dominated the clinical picture.

In 187 cases there was occasional or less often constant albuminuria in association with acute infectious diseases, gout, diabetes, tuberculosis, syphilis, cystitis, pyelitis, cardiac diseases, movable kidney, gallstones and jaundice, stone in the kidney, in occasional cases of other diseases, in pregnancy, and in adolescents without discoverable disease.

In 11 cases, in gouty or so-called lithemic subjects, there was occasional albuminuria at times when the urine was excessively acid.

In 215 cases (37 per cent.) there was no albumin at any time. In 11 cases casts were found without albumin.

I am ready to admit the unreliability of statistics, but would vouch for the essential accuracy of these figures. It might seem at first that urinary examina-

tions are of little value, if out of 581 cases albuminuria without Bright's disease occurred in 202, no albuminuria in but 215, and as an indication of Bright's disease in only 51. Closer examination of the records, however, establishes several important points.

With very few exceptions, the albuminuria of the supposedly non-nephritic cases was qualified as "albuminuria in traces," and with nearly equal frequency repeated examinations showed that the condition was fluctuating in degree or temporary in duration. The exceptions to these rules were for the most part cases of arteriosclerosis, in which, as I have said, there was doubtless always a greater or less degree of chronic interstitial nephritis, though the renal manifestations were not generally predominant.

To establish the frequency of albuminuria in cases of severe acute infections and in cardiovascular diseases I have collected the data obtained from my records at the University Hospital. Summarizing the records of a great variety of infections, it is found that among 176 cases albumin was present in 59 and absent in 117. Among 304 cases of typhoid fever albuminuria was present in 83, clinical nephritis in 14, and albuminuria was absent in 207.¹

Among 154 cases of cardiovascular disease, albumin or casts, or both, occurred in 81, and neither albumin nor casts in 73.

Table 1 shows the conditions in different types of such diseases:

No.	Disease.	Albumin and casts.	No. Albumin.
1.	Acuerism.	6	15
2.	Arteriosclerosis	10	6
3.	Myocardial disease	10	8
4.	Malignant endocarditis	3	3
5.	Aortic valve disease	8	7
6.	Mitral disease	29	26
7.	Combined valve disease	15	10
Totals		81	73

In considering these figures it must be remembered that a certain number of the cases were instances of combined cardiac disease and Bright's disease, but it is equally clear that the large proportion of cases of albuminuria require a further explanation.

A careful scrutiny of the clinical course of these cases of cardiovascular disease showed that almost without exception the condition of the urine was extremely variable, and fluctuated in correspondence with variations in the underlying condition, so that the degree of albuminuria was in a measure commensurate with the degree of cardiac insufficiency.

I wish to refer very briefly to the occurrence of albuminuria in cases of secondary syphilis, because I have found in a number of cases that the discovery of albumin has been looked on with great apprehension. My experience in this field has naturally been limited, and I content myself, therefore, with calling attention to the fact that slight or sometimes considerable albuminuria is not infrequent in the secondary stage of this disease. It has seemed to me that active mercurial treatment might in some instances be the responsible agent, but I am sure that slight albuminuria occurs independently of this, and in my experience it has proved a matter of no serious moment.

1. In explanation of the lower proportion of non-nephritic hospital cases showing albuminuria as compared with my private cases, I must explain that the examinations in the latter were made with much more care to detect even the slightest traces of albumin. In addition to the greater experience of the examiner, an important factor in this greater accuracy was the use of a reflector of urine which gives a light specially favorable to the detection of faint turbidity in the liquid tested. The method used was to heat only the upper part of the column of urine in the test tube.

Another subject on which I wish to say a few words is that of the special form of albuminuria found in amyloid disease of the kidneys. It is well known that in chronic forms of albuminuria, the serum albumin is in great excess of the globulin. The conditions are reversed in amyloid disease to such an extent that preponderance of globulin in a chronic case warrants a strong suspicion of amyloid disease of the kidney. In several cases I have in this way been able to recognize this condition even before sufficient amyloid disease of the liver or spleen had occurred to enlarge these organs and to make them palpable.

In conclusion, let me say that the purpose of this paper has been primarily to direct attention to the fact that albuminuria is an extremely common occurrence in various general diseases and that, though it may in a sense indicate an inflammatory condition of the kidney, such inflammation or nephritis may be of merely pathologic rather than of clinical significance, unless the albumin is considerable in amount and more or less constant in occurrence. The nature of the accompanying tube casts must not be relied on too greatly to determine the seriousness of the renal lesion, and in particular the presence of an occasional hyaline cast or even the frequent occurrence of such must not be regarded with too much apprehension. The modern method of centrifugation and the consequent examination of quite fresh urine increases the likelihood of our finding casts, and there is often difficulty in distinguishing between the insignificant cylindroid of the mildest grades of renal irritation and the definite hyaline cast of more decided disease. Even the latter, however, is so frequent in cases of arteriosclerosis, cardiac disease, hepatic disease, jaundice and gouty affections without serious renal disease that its significance is more or less trivial, unless general clinical conditions accentuate the importance of its presence. I do not wish to convey the wrong impression that I estimate lightly the importance of urinary examination; far from it. But I know from much experience that a trace of albumin is too often magnified in importance in the physician's mind, and that the clinical conditions as a whole are not sufficiently considered. Above all things, it is important in cases of suspected renal disease that the urine be repeatedly examined and its constant or fluctuating condition be taken into account.

CYLINDRURIA.

CHARLES P. EMERSON, A.B., M.D.

Assistant Resident Physician in Charge of the Clinical Laboratory,
Johns Hopkins Hospital; Associate in Medicine, the Johns
Hopkins University.

BALTIMORE.

The subject of casts in the urine has been a favorite one for study in the clinical laboratory of the Johns Hopkins University during the past five years. In addition to such studies, this paper contains as its most important portion the report of a study of the records of all the cases of nephritis admitted to the medical wards of the Johns Hopkins Hospital, over 1,000 in number, about 500 of which came to autopsy, together with other cases clinically resembling nephritis but with no anatomic evidence. I and my associates in the laboratory wish to express our indebtedness to Dr. Osler for the use of this abundant and most valuable material.

CASTS; THEIR CLASSIFICATION AND FORMATION.

Casts have been classified as cellular, granular and amorphous. The latter show no structure, being homogeneous or at the most with only a faint striation. All combinations of and transitions between these forms occur.

(1) *Epithelial Casts.*—These are made up of, or have attached to them, renal epithelial cells; that is, cells which vary much in size but have always (when it is visible) a round nucleus. The cells are flat and polygonal as a rule, not spherical. The protoplasm is usually (always?) very much degenerated, the cell being but a mass of fat, myelin, or albuminous granules, which may swell the cell to a great size. When these cells retain their finer structure, which is not often, they are considered to resemble those from the straight collecting tubules, not the secretory cells. An epithelial tubule could not pass a loop of Henle of normal bore, but single cells or the detritus of cells from above could attach themselves to a cast forming below. Most epithelial casts are masses of epithelial cells united by a hyaline matrix, but some are certainly desquamated portions of the tubules with the lumen, and with even the intercellular protoplasmic bridges visible. In one kidney which we have had an opportunity to study, in sections at the juncture of cortex and medulla the invaginated tube of epithelium could be beautifully seen, which, breaking loose, would be a cast. That is, at these portions were two tubes of epithelial cells, the intact one lining the tubule and an invaginated also intact interior one, evidently loosened and rolled down from above. Such perfect fragments are called "epithelial tubules." This being the origin, it is the free surface of the cell which forces outward the base lining the lumen.

All transitions between these and the coarsely granular and fatty casts are seen, and the question arises where to draw the line. In this laboratory we consider the cast epithelial if the cell outline of one cell with a round nucleus can be made out.

Also a hyaline cast with one epithelial cell attacked ranks as an epithelial cast.

We doubt, with Cabot, that all the mononuclear cells are renal; also that from study of the degenerative changes or "atrophy" of these cells any conclusions concerning the changes in the cortex can be drawn, yet we believe that the cuboid or flat polygonal cells are of renal origin.

(2) *Coarsely Granular Casts.*—All transitions between epithelial, leucocyte and these casts can be found. These are of a yellowish-brown color, very opaque, hence conspicuous objects, covered by coarse granules. Some of the granules are soluble in acetic acid, hence of albuminous nature; others are soluble in ether and take the fat stains; still others resemble the myelin of the sputum. These casts are probably either epithelial casts the cells of which have undergone degenerations, or are agglutinations of the detritus of epithelial cells which have gone to pieces in the tubule before or after desquamation.

In the laboratory we have had occasion to study another form. In cases of subacute nephritis large cells sometimes occur, two or three times the size of an ordinary renal cell, or even larger, which are masses of fat and myelin droplets and resemble colostrum corpuscles. We believe these to be of renal origin. In some cases these cells occur in rows of two or three; in others the cell divisions are indistinct, while still others form typical granular casts. Among

*Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

the coarsely granular casts are included hemoglobin casts, which are of a brownish-red color.

(3) *Fatty Casts*.—These striking objects are masses of fatty granules often preserving the outline of the original epithelial cells. They are yellowish or even blackish in appearance and soluble in ether; fatty acid crystals may project from them. The fat globules may be enormous, almost as large as a cell. They occur especially in malarial nephritis.

(4) *Finely Granular Casts*.—The term "finely granular" is indefinite. It includes casts very similar to the coarsely granular save that the granules are much finer; also many with little resemblance to these latter, since they are almost translucent, much smaller, less conspicuous, and are covered by, or have scattered over a part, very fine granules which are seen to belong to the cast and not to be a mere deposit on a hyaline cast; many of them are intermediate in appearance.

(5) *Waxy Casts* (also called colloid or amyloid).—These casts are very refractile, sharply contoured, often of a white or yellow color, homogeneous, and show a great tendency to split transversely, hence they are fissured and are often in small fragments. They may have, rarely, cellular elements attached. They show a marked tendency to spiral twisting. Two groups are present, the clear white and the yellow; the first look as if cut from paraffin, the second as if from wax. They seem to be formed of a stiff, firm, brittle material. They look broader than the hyaline casts. Some give the amyloid reaction as a whole, some in portions; more do not, and the reaction is seldom really satisfactory. Some observers deny having ever found a good amyloid cast (Cornil). They are quite resistant to acetic acid.

The name "waxy" is best since it signifies only physical properties, not chemical, as the term amyloid does.

Between this group and the hyaline casts is a very large group of casts which are perhaps the commonest of all, which have not quite the physical properties of the waxy, yet are more distinct and solid-looking than the hyaline, which name they bear. It is important to recognize that some of these have deposited on them fine granules from the urine, giving them the appearance of the finely granular cast.

(6) *Hyaline Casts*.—There are the colloid or glassy casts. They are pale, very slightly refractile, watery in appearance and difficult to see unless the light is almost shut off or unless one notices crystals or cells sticking to them. For this reason, and because they are so often few in numbers it is better to stain them with Lugol's solution, which gives a yellow color, or with gentian violet. If low light and no condenser be used, however, this is unnecessary. They give the microchemical tests of albumin. They may have the same cells attached as the other casts. They are beautifully cylindrical, with rounded ends, a uniform diameter as a rule but not always, may be either broad or very narrow, and sometimes are twisted like a corkscrew.

Hyaline casts sometimes have a fibrillar appearance and may disintegrate, in which case they resemble a Curschmann spiral in miniature; that is, these consist of spirally wound threads.

Branching casts have been described. Some taper considerably along their length. Their outline is very regular. These casts occur in all conditions, but this is the only form which follows certain disturbances in which there is no question of inflammation. They are so different in appearance from the hyaline casts just mentioned as "intermediate" that they really deserve a sep-

arate name. They are easily dissolved by acid, or alkalis, are soft, elastic, and easily destroyed by cold or heat. They are the most important to recognize since they occur so often alone. They are the first to disappear in a urine which is becoming alkaline, hence the freshly voided urine should be centrifugized and studied on a broad slide without cover-glass, which is covered well with the urine, and using the low power. Several slides should thus be examined before the search is abandoned.

Hyaline casts seem to be the ground substance for most epithelial, pus and blood casts, and hence for most of the mixed variety; one end of such a cast may be purely hyaline.

(7) *Blood Casts*.—Blood casts are a coagulum of red blood cells which have formed within the tubules. The term is also applied to any of the above casts with red blood cells attached. Some of the blood cells are so pale that it is hard to recognize them. Many have crystals of hematin attached.

(8) *Hemoglobin*.—Casts of hemoglobin occur in hemoglobinuria, the hemoglobin occurring in amorphous masses. Some seem to be other casts impregnated with hemoglobin.

(9) *Fibrin Casts*.—These are rare, if even they ever occur. They are opaque, granular, longitudinally striated, often ribbon-like and twisted, often fibrillar and branched at their ends; in them are mixed fragments of blood cells and granules of pigment.

(10) *Pus Casts*.—These have a formation similar to that of the blood casts. The nuclei must be first seen and their polymorphous nature decided, to be sure it is not an epithelial cast. This may be done by adding acetic acid. Pus cells are smaller, more spherical and finely granular than the epithelial casts.

(11) *Cylindroids*.—We should prefer to separate these into two groups. The first are the so-called "mucous threads." Some are short, some are very long extending through several fields, singly or in snarls. They are flat ribbons of mucus which no one would confuse with a hyaline cast. Their diameter varies much, but on the whole they are narrower than hyaline casts. They are not cylindrical, but ribbon-like, as is well seen in their twists. Such threads make up the nubecula. They usually are branched and taper off into threads the ends of which it is almost impossible to see. They have a finely striated surface, sometimes finely granular. They do not dissolve on adding acetic acid.

(12) *Other Elements*.—In addition to these, and differing much from them in appearance, are seen elements which appear exactly like hyaline casts for the most of their length, but which at one end run off in a longer or shorter thread. They are often broader than hyaline casts, and are frequently not strictly cylindrical, but somewhat club-shaped. Those observers who are particular on this point exclude from the list of casts anything which has one end at all tapering or thread-like. These casts appear to be circular on cross section. They have not always the same fibrillar nature and are more refractile than mucus threads, hence are easily picked out in a snarl of the latter. They occur also in those circumstances in which casts would be expected and have the same significance. They occur when only a few hyaline casts are present, but a trace of albumin, and when the acetic acid precipitating body is abundant; we have often been tempted to associate them in some way with this body. We are certain that for the greater part of their length they are like typical hyaline casts, and could the fine end be broken off, as we sus-

pect is done by the centrifuge, the fragment without the tail could not be distinguished from a cast. Like the mucous threads and hyaline casts these threads may be covered by urates and hence have the appearance of granular casts. These, like hyaline casts, and differing from mucous threads, often have cells or detritus of cells attached. Chemically these bodies are like casts and are soluble in acetic acid. The point is of considerable importance, for mucous threads certainly arise from the mucous surface, while if casts they should arise in the renal parenchyma. They were first described as of the same significance as casts. It is perhaps safest to observe the old rule and exclude from the list all which have a definite tail on one end, and if, as often happens, one is in doubt to call it a cylindroid.

(13) *Combined Casts.*—These comprise nearly all the casts in most cases, and they are the hardest to classify. It is customary to call a cast with a recognizable epithelial, pus, or blood cell attached to a cellular cast, an epithelial, pus or blood cast, although many workers prefer to use the term "hyaline with leucocyte attached," etc. The most common mixed casts are hyaline and finely granular, or waxy and coarsely granular.

(14) *Bacterial Casts.*—Masses of bacteria in the shape of casts occur in purulent infectious pyelonephritis and in pyemic kidneys, but a cast also may become permeated by bacteria, either in the body or after being voided in the urine, in a remarkably short time.

(15) *Urate Casts.*—In uric acid infarcts of the kidneys of the newborn, masses of sodium urate may be found in the urine.

(16) *"Pseudo Casts."*—This term is used by some observers (Neubauer and Vogel), to mean a cast which is not a mould of the tubule, formed of some homogeneous material, hence the term included epithelial, pus and blood casts; but the term, we believe, should apply to origin, and the question is: Does it come from a tubule? It is not at all unusual for an urate sediment to assume the shape of a cast. All casts in a concentrated urine may become encrusted with urates and hence be of a dark, homogeneous granular nature. True granular casts are not homogeneous; they are coarser and more refractile than these pseudo casts which also have uneven edges and disappear on warming. Other salts forming such casts are uric acid, calcium oxalate phosphates, sodium urate and ammonium urate. Scratches on the glass are sometimes confusing.

Characteristics of Casts.—The length and the breadth of casts vary. Usually they are from .005 to .05 mm. in width. Their size may be from very small fragments to 1 mm. in length or longer. These very long casts are almost always hyaline. Some casts are almost on the limit of vision, but vegetable fibers must be excluded. Their diameter is that of the tubule. From the size of the casts no conclusions can be drawn of their source, so much does the size of the tubules vary in various conditions. It was formerly supposed that the beautiful corkscrew forms so often seen came from the convoluted tubules, but this is improbable, since any corkscrew shape would certainly be effaced during the passage through a straight tubule. Some are spiral all their length; others only at one end. This, says Senator, merely shows them to be composed of a tough, elastic material which has been squeezed through a narrow canal, or through a narrow orifice. The end of the cast is seldom split or forked.

Origin of Casts.—The origin of epithelial casts, especially of those with a lumen, is not disputed; yet they mean not necessarily a serious lesion, but merely des-

quamation of epithelium such as occurs from all mucosae as the result of "catarrhal" inflammation; neither is the origin of blood and pus casts disputed. We believe these casts, the epithelial, blood and pus, to be much more common than the usual urine records would indicate, perhaps since the general belief that they indicate a rather serious condition leads one to misinterpret or to pass them by when found in some trivial condition. As a matter of fact they occur whenever there is an acute, that is a sudden, disturbance of the cells, whether inflammatory or not. The coarsely granular casts quite certainly are formed from epithelial by a granular degeneration of the cells to the waxy casts, and all transitions from the coarsely granular may be found. This transition may also occur in the leucocyte casts, but is less true of the blood casts. Such transitions are supported best by the study of sections of the kidney.

The rapidity with which waxy casts may appear, unaccompanied by epithelial and coarsely granular casts, and the transitions between them and the hyaline, lead one to suspect that they differ from the refractile hyaline in only physical properties. One explanation is that they are hyaline casts which have remained in the tubules a long time and the originally hyaline or granular substance has become waxy through "amyloid metamorphosis." The sudden appearance of waxy casts may mean merely the washing out of those long in the tubules. We do not believe that the transition from epithelial cast to coarsely granular and from these to finely granular, and then to waxy, applies in most cases, but may for some. These transitions can not be followed in the casts when these are in the urine. Against this theory may be mentioned the sudden appearance of enormous numbers of one group without a corresponding increase of the so-considered previous stages. Waxy casts may appear in great numbers in the few last hours of life; the finely granular transparent casts in their occurrence bear almost no relation to the coarsely granular, as is best seen in the Kulz sign of oncoming diabetic coma. Yet the general ideas of their origin may still be true, and some casts may depend on the disintegration of the epithelial cells, by which they are formed; this disintegration, together with abnormal secretion, occurs in the cell while it is still a part of the tubule and exposed to the toxins, etc., in the blood. That changes in the cell thus situated are sometimes rapid we are sure, but the free cell will not go to pieces nearly so rapidly as is imagined. At least the changes, whatever they are, occur in the tubules, not later. It is true that the casts show transitional forms, and that in one case two forms may be combined, but this could have been determined during the process of formation, as well as later. The importance of this intratubular determination of form is best seen in the waxy casts. These occur when the casts remain a long time in the tubules. Those in closed tubules are waxy; the casts following an oliguria are often waxy, which is seen best in cases of decapsulation of the kidneys for subacute nephritis. We can not give any better explanation for their appearance ante-mortem.

The origin of the hyaline casts, however, has long been in dispute, some observers claiming that they are an exudate into the tubules, others that they are a product of the secretion of the cells. These casts are certainly not coagulated fibrin, since they arise where there is no suspicion of inflammation, that is, in a practically normal kidney, as with the albuminuria of the newborn. The typical hyalines do not give the Weigert's fibrin

stain. Two sources are possible: (1) That they are formed from the coagulated albumin of the blood serum, which escapes from the glomeruli, or perhaps, when diseased, through the tubules, and coagulated possibly by a ferment from the renal cells. Cylindruria, therefore, is visible albuminuria. According to this view, the difference between hyaline and waxy casts would be the amount and rapidity of excretion of this coagulable albumin, and the time it remains in the tubules. It is an interesting idea that such albumin should coagulate, for where a certainly coagulable albumin is present, as in the case of chyluria, these casts are absent; also there is little relation between albumin and casts in amount, and either may be present without the other, yet albuminuria and cylindruria run too parallel to be independent. The one may always at least be suspected when the other is found, and in nephritis especially in their amounts they have a very definite parallelism. According to this view the materials for the casts escape some distance from the point where this material is collected and formed into a cast. (The ascending branch of the loop, the straight and the collecting tubules.) (2) Other observers (Key, Beyer, Senator, Langhans) claim that these casts originate in the epithelial cells. From sections of kidneys all steps of the process may be traced. In some cases epithelial cells die and undergo hyaline degeneration, and this substance may be molded to the cast; or the epithelium may die and allow lymph to transude into the tubule which, mixing with the cell detritus, coagulates; or (Oertel, Bartels, Rodiva, Aufrecht, Cornil, Brault) the very slightly injured epithelial cell still functioning may secrete a coagulable substance. This latter is the generally accepted idea. Some cells are seen to be swollen by globules; others have excavated edges, that is the vacuoles full of albuminous matter are discharged into the tubules and there fuse.

The origin of hemoglobin casts is interesting, since hemoglobin is soluble in the urine. It may be, however, that they represent hyaline or waxy casts impregnated with hemoglobin.

Chemistry of the Cast.—The chemistry of the cast is little studied. Probably none are fibrin. Some give an amyloid reaction when there is no such degeneration of the kidneys; amyloid disease rarely has such casts. Many react reddish to gentian violet; and brownish to Lugol's fluid.

A STUDY OF THE CASTS IN A SERIES OF CASES OF NEPHRITIS AND OTHER CONDITIONS.

We are obliged to consider other things than casts alone, albumin, etc., in this study that the picture of the cylindruria may be clearer.

Active Congestion of the Kidneys.—In one case of acute lobar pneumonia without, as yet, nephritis and with the kidneys actively congested, the weight was 425 grams, the depth of the cortex 7 mm. The urine was normal in amount, of a high specific gravity, with considerable albumin and a very few finely granular casts.

Chronic Passive Congestion.—In the urine, at first scanty, dark in color, and acid, albumin appears sooner or later in traces, although sometimes in good amount. Casts are present, chiefly hyaline, rarely granular, more rarely other varieties. A very few leucocytes may be found and still fewer red cells. The points of importance in this urine are the small amount of albumin, the large urate sediment, the comparative absence of renal epithelium, and the scarcity of granular casts and leucocytes.

Of 11 cases of extreme chronic passive congestion, chiefly heart cases, yet anatomically with no microscopic sign of nephritis, in 8 the clinical diagnosis of nephritis had been made. The average weight of the kidneys was 390 grams. The cortex averaged 8 mm. in thickness (7 to 10 mm.). The amount of the urine varied with the cardiac condition, being either normal or diminished in amount. The specific gravity was high, running from 1025 to 1027 in some cases, and in but 3 cases below 1015 for much of the time. Albumin was present in all cases; in one-half of them there was only a trace, but in others large amounts, even 0.6 per cent.

Castes were abundant in 3 cases and absent in but 1; as a rule they were few in number. Here in 3 cases, as in other conditions, on some days, they were present in extraordinary numbers; on other days there were few, and these chiefly of the hyaline and granular varieties, but in some cases epithelial, pus, waxy and fatty were found.

Cloudy Swelling.—Twenty-three cases were chosen which at autopsy showed extreme parenchymatous degeneration without other evidence of nephritis. Nine of these cases were of typhoid fever, 4 of pneumonia, and the rest scattered, but all fevers. In 1 case of typhoid fever the clinical diagnosis of uremia had been made.

The average weight of the kidneys was 410 gm. (250 to 590 gm.) The cortex averaged 7.5 mm. thick (5 to 12 mm.). The urine of these cases voided from one to two days before death varied in amount from 500 to 1,900 c.c. and was of a rather high specific gravity (1015 to 1028). This varied inversely as the amount. In one case the specific gravity was for several days 1004, the amount averaging 1890 c.c. In the specimens just before death, albumin was present in traces in 12 cases, much in 3, and none in 2. The albuminuria had continued in some cases for two or three weeks; in one case the first record of its presence was 34 days before death; in the other cases it appeared much later. In 2 cases examined one week before death no albumin and no casts were present.

Almost all varieties of casts were present, particularly hyaline and granular, but also blood, epithelial, and waxy. Few were present as a rule; in 3 cases large numbers. Two cases were without albumin and without casts even to the very time of death. One was a case of tertiary lues of the brain, the kidneys showing exquisite parenchymatous degeneration and the urine a specific gravity of 1008, yet even on the day of death there were no casts and no albumin. In typhoid fever cases with the bacilli present in the urine in large numbers, repeated examinations showed no casts, although a fair amount of albumin was present. As a rule, the casts appeared later than the albumin. In one they were very numerous on the last day of life. In 4 cases red blood corpuscles and epithelial cells were present.

Fatty Kidneys.—In the severe cases of fatty degeneration or infiltration of the kidneys the amount of urine is diminished, dark and cloudy, although it may be normal in amount. The urine is present in from traces to considerable amounts. The casts are chiefly hyaline and granular, some are fatty; there are a few red blood cells and a few leucocytes, although in some cases, many. There seems to be no relation between the number of casts and the amount of albumin.

We chose from our autopsies 7 cases with extreme amount of fat in the cortex and, microscopically, no other chronic change. The average weight of these

was 380 grams (250 to 530); the cortex was from 6 to 8 mm. thick. The amount of urine was normal, and the specific gravity varied from 1020 to 1024. The albumin was considerable in about one-half of the cases, and there was only a trace in the others. In no case was albumin found two weeks before death.

The casts were hyaline and granular, few or many, the number bearing no relation to the amount of albumin. In 2 cases a few red blood cells were found, and usually some pus or epithelial cells.

ACUTE NEPHRITIS.

Acute nephritis has been divided into several various groups, chiefly from the standpoint of pathology, but for the clinician a division is very difficult. Senator separates the tubular nephritis or acute parenchymatous from the acute diffuse. In the acute parenchymatous form the tubules especially are involved and the glomeruli little or not at all. The clinical symptoms are slight or none. The urine shows only slight febrile albuminuria, diminished amount of urine of rather high specific gravity, and few or no casts. The mildest grade is simple cloudy swelling and from this are all gradations to the acute diffuse nephritis. The urine contains often a heavy sediment, in some cases chiefly of renal epithelium, and hence the name "nephritis desquamativa." The epithelial cells may be single or in casts. Hyaline casts, few or many, are present. Crystals of uric acid and calcium oxalate, red blood corpuscles are often present, and hemoglobin in granular casts or masses. The leucocytes are usually few in number. The albumin is nearly always slight in amount, in remarkable contrast to the amount of sediment, and some claim that of this nearly all is nuclealbumin from the cells.

In the acute diffuse nephritis, a good illustration of which is that following scarlet fever, the urine is diminished in amount; there may, indeed, be anuria for the first 24 hours. From 50 to 100 c.c. for the first day or so is not uncommon, but later from 200 to 500. Of 16 such cases in our series the weight of the kidneys averaged 430 grams (360 to 500), and the cortex averaged 8 mm. (It is interesting to note that the heaviest kidneys were in women.) In these cases the amount varied from 30 to 2,000 c.c., according to the stage of the nephritis. Toward death there may be a diminished or an increased voiding. The specific gravity was normal as a rule, from 1015 to 1017, but in some cases it was from 1023 to 1025 (when the urine was from 200 to 600 c.c.). It is usually of a dark color and cloudy, and blood is nearly always present, as pigment or cells.

Albumin is an almost constant feature, and yet in some severe or fatal cases there may be but traces, and this only on a few days, alternating with periods with none, even to death. As a rule it is not above 1 per cent. In the sediment may always be found red blood cells, mononuclear cells, few polynuclear leucocytes and epithelial cells from the urinary tubules, which are single or in masses, and often very fatty. Among the crystals uric acid and calcium oxalate are found, and hemoglobin, either in amorphous granules or in casts. In the hemorrhagic form of the disease in our series the red blood cells were remarkably few in number. The leucocytes were very abundant in one case of acute nephritis with multiple abscess.

Casts are present in varying amounts and may be of any form. Epithelial, hyaline and coarsely granular predominate. Blood and leucocyte casts may also be present. As a rule, the number runs parallel to the

amount of albumin, yet it varies greatly from day to day, and on some days there may be enormous numbers. In one case of acute hemorrhagic nephritis with areas of complete necrosis the amount of albumin was slight, but the casts, leucocyte and granular, were in large numbers. In one case of general septicemia the albumin was in but traces on certain days, none on others, and yet blood, hyaline and leucocyte casts were found.

In mild cases, and in severe ones as they improve, the urine approaches normal. It is said that the albumin disappears last. In most cases, however, we believe that the casts are found later.

Among our cases of nephritis were 109 of the acute form. Of those patients who recovered 64 were under 45, and 17 were over 45 years of age. Thirteen unsuspected cases were found at autopsy. In eleven cases a diagnosis of acute nephritis was corrected at autopsy, 2 being unsuspected cases of large red kidney, 1 of large white kidney, 6 of subacute nephritis and 2 of the small white kidney. Twenty-six patients were admitted during the first seven days of their illness. In these cases the urinary symptoms were almost parallel with the clinical symptoms and especially with the amount of edema. The urine varied ordinarily from 200 to 300 c.c. for 24 hours, with a high specific gravity, from 1020 to 1030, those with a high specific gravity being in all cases those with much albumin. In 11 of 26 cases this was over 1020 and in 3 cases over 1030. The amount of albumin varied much, being above 1 per cent. in 1 case, above 0.5 per cent. in 6, and in traces in 5. In all of these with traces the specific gravity was under 1018. Casts of all varieties were present—hyaline, granular, epithelial, blood and pus, and waxy in but 1. The cells which were usually present were epithelial, red blood cells and pus cells. During the course of these cases in the hospital the amount of urine increased even above two liters and in 4 cases of the 25 above four liters. The albumin dropped to a trace or to none, and the casts continued, in those previously mentioned, while waxy and fatty casts also appeared. In nearly all cases in which albumin disappeared, the casts continued longer. At the end in those not doing well there was much albumin with many casts. In this series of cases the patients did much better than those admitted later in their disease. There was little difference in the course, for those appearing with traces and those with large amounts of albumin, although the difference was in favor of those with traces. These may have been admitted after the worst was over. In those patients admitted later, for instance between the seventh and fourteenth days, 12 in number, the amount of urine averaged 9.50 c.c., in 4 over 1,500, and in 1, 3 liters. The mean specific gravity was 1015, the average 1018, and the extremes 1003 and 1030. The albumin was constantly present in larger amounts than in the first series. In 6 of the 12 cases there was over 0.5 per cent., and in only 2 were traces present. The casts were hyaline and granular, but sometimes epithelial (in 5) and blood. In one case a shower of casts followed the patient's getting up from bed. In these cases the albumin lasted longer than the casts.

Thirteen patients were admitted during the third week of the disease. Five of these had only traces of albumin; others, much. There were hyaline or hyaline and granular casts in 7 cases (those with fair urine output), epithelial and blood also in the others, in which latter group are the patients with considerably diminished output of urine (in no case over 900 c.c.).

Twenty-one patients were admitted after the third week. These were either on the road to recovery or doing badly as a result of their previous poor condition. The amount of urine varied from 3 to 4 liters in six cases. In some, the amount of albumin was very large, even over 1 per cent. Nine of these patients did poorly and we have the notes of the ultimate recovery of but two. The casts were hyaline alone in 1, hyaline and granular in 6, especially the older patients, epithelial also in 8, blood also in 9, leucocyte in 3, waxy in 2.

SUBACUTE NEPHRITIS. CHRONIC PARENCHYMATOUS NEPHRITIS. CHRONIC DIFFUSE, NON-INDURATIVE NEPHRITIS. LARGE WHITE KIDNEY.

This form of subacute nephritis, which may follow an acute attack or develop without this, is characterized by its subacute course, and often by the large amount of edema and effusions usually present in the serous sacs. It occurs especially in young persons, hard workers in exposed, unhygienic surroundings, and as a result of constitutional diseases, tuberculosis, lues, malaria, especially, also alcohol. The diagnosis is usually easy from the history.

The amount of urine is always diminished, the diminution varying as the edema, and is especially small at death. At the height of the disease it varies from about 250 to 500 c.c., but as the case improves, one may void from 5 to 6 liters of a very dilute urine. The amount also is increased as the edema or the effusions begin to absorb. The reaction is faintly acid, but in some cases is alkaline even on voiding, and in all cases quickly becomes so. This makes a search for casts difficult.

This is the form in which the albumin is greatest in amount, both relatively and absolutely. The amount varies as the specific gravity and seems to bear no relation to the edema. It usually is below 1 per cent., and for months may vary from 0.4 to 0.8 per cent. In certain cases, however, it is much greater. Cases with 2 per cent. are not rare, and Bartels has reported a case in which the amount varied from 4 to 6 per cent. As the case changes to the chronic indurative form the amount of albumin becomes less and less.

The sediments are much the same as in acute nephritis but it is more common to find coarsely granular, fatty and waxy casts. Red blood cells may practically always be found in especially large numbers in the acute exacerbations. There is little difference between the urine of the white and the mottled kidneys except perhaps that in the latter there are more red blood corpuscles, leucocytes, and fatty cells.

We have studied the reports of a series of 30 cases in which microscopically only the signs of subacute nephritis were present. This is important, since the acute exacerbation of a chronic diffuse nephritis can not clinically be separated from this form. These cases may be roughly divided into those in which there are large, pale kidneys, with considerable fatty and granular degeneration of the cells but with the glomeruli little involved, those with the glomeruli much involved, and the hemorrhagic type. Of the former, of 16 cases in 12 the clinical picture was of severe nephritis. Four accompanied various severe conditions, such as septicemia, tuberculosis, typhoid fever. The kidneys were large, averaging 420 grams in weight (220-580 gms.) The cortex averaged 7 mm. (5 to 10 mm.). The urine, for the most part, was about 500 c.c. in 24 hours, with a specific gravity practically normal. The albumin in 7

cases was present in large amounts, from 0.5 to 1 per cent.; in 5 cases there were but traces. Casts were abundant in 5 cases, hyaline, granular, epithelial, waxy in 4 and fatty in 3. Epithelial, red blood cells, and leucocytes were present. In this form there was a certain disproportion between the amount of albumin and the number of casts in favor of the latter.

In 8 cases the glomerular involvement was very prominent. The kidneys averaged in weight 496 grams and the cortex 9 mm. The amount of urine was slightly greater than in the preceding cases (from 600 to 1,000 c.c.), and the specific gravity about 1020. The amount of albumin was large in 5 cases. Casts were very abundant in 4; in 2 the casts were in great numbers and the albumin was but a trace. No fatty casts were reported in this group.

One would expect that a glomerular involvement would affect particularly the amount of albumin, the tubular involvement especially the number of casts, and while in general this may be true, clinically it is of little importance since the two anatomic conditions are always present and variations are but slight.

Hemorrhagic Form.—Of the 9 cases showing this form of nephritis, in five it was part of some general disease. The kidneys averaged 465 grams. The amount of urine was normal, the specific gravity low. Albumin was present but in traces as a rule. Few casts were present but of all varieties, and in one case with but a trace of albumin, many casts.

CASES OF CHRONIC NEPHRITIS WITHOUT AUTOPSY.

These were cases of a subacute or chronic nephritis with very acute symptoms, much edema, and effusion.

It is impossible to say whether these cases were acute exacerbations of a chronic nephritis or a subacute form. We have therefore merely divided them into two groups, those under 40 (in this group a majority of the subacute cases should occur) and those above 40 years of age.

Of the patients under 40 years of age there were 129. Of these 70 could give no cause, in 10 it seemed to follow malaria, 14 exposure to cold, and 6 grippe. The others followed a variety of diseases.

There were 61 cases with much edema. In 49, or 80 per cent., the urine presented the following features: it was normal in amount and specific gravity; albumin large in amount, in 20 per cent. over 1 per cent., in 4 cases over 2, and 1 case 3.2 per cent. The casts were in enormous numbers—hyaline, granular, epithelial, fatty, waxy, pus, and blood, in all cases in number out of proportion to the amount of albumin. Among the cells are always found renal epithelium, blood, and pus. In 2 cases cholesterol crystals were found.

In 11 of the 61 cases albumin was present in but traces, and in 1 case none yet many casts.

Of the cases with little edema there were 68 patients who left the ward improved; in 44 per cent. of these the urine presented exactly the same features as the 49 cases above described. Of the rest, in 38 but a trace of albumin was present, in 3 above 1 per cent. Of these in 15 per cent. of the cases the casts disappeared before the albumin and the disproportion was not so great between the two. Yet the relation between the two must depend on the nature of the process, and not its chronicity, since in exactly the same percentage of the cases with a history of less than 6 months' illness did the casts disappear before the albumin as in the much more chronic cases. In this group were also 10 fatal cases. Of these, in 3

there was but a trace or no albumin at the end, in 7 cases more than 0.2 per cent., in 1 case 1.1 per cent.

Subacute Nephritis (or Acute Exacerbations) in Patients Over 40 Years Old.—Of these, excepting the fatal, there were 45 cases. In 28, the first symptom had occurred within six months of admission; in 7, between 6 and 12 months, and in 10, anywhere from 1 to 35 years. No clinical division of this group was possible, hence we group them according to the urine into the following groups:

Cases with a trace of albumin, the amount and specific gravity practically normal; albumin but a trace, and casts only hyaline and granular; cases with a measurable amount, but under 0.2 per cent.; the casts were of many varieties, hyaline, granular, epithelial, waxy and blood casts were found; and cases, in which there was still more albumin, all kinds of casts were present, including many epithelial, fatty and waxy. In these last cases the casts were sometimes in the background, while in 1 case of leucic nephritis with 2.2 per cent. in many records no casts were found at all. In other cases, all kinds and many were found. In addition to these, there were 10 fatal cases; 4 of the patients died with traces of albumin; of these 1 had enormous numbers of casts, all granular and hyaline; 2 had few casts. In 4 the albumin was greater in amount, the casts either hyaline or hyaline and granular, and in 2 cases none. In 2 cases there was over 0.2 per cent. albumin, with hyaline and granular casts.

CHRONIC INTERSTITIAL NEPHRITIS.

Chronic interstitial nephritis, even in advanced cases is marked by its very insidious course. Its only symptom may be a slight albuminuria, and this may be absent over long periods. Later the albumin becomes permanent, casts appear, and later polyuria. The urine is increased slightly at first, but in a well-developed case from 2 to 3 liters are voided daily, and rarely even as high as 12. On the other hand the amount may at times sink to normal and even under. It is pale, clear, definitely acid, and of a specific gravity which is constantly between 1010 and 1005. This low specific gravity of a morning urine is always significant of this condition. The molecular concentration is diminished. The albumin seldom rises above .05 per cent. and usually is in mere traces. Casts are few. They are often absent in the morning voiding and may, indeed, be present only after a day of unusual exercise, or an especially hearty meal or some unusual excitement.

Of arteriosclerotic kidneys the urine contains the faint trace of albumin which occurs late and is often intermittent. Cases of the so-called contracted kidneys, particularly those albumin-free, belong here. The sediment is scanty and difficult to find. The urine should be centrifugalized and search made in large amounts of urine. After a long search but one or two casts may be found, usually hyaline, although sometimes a finely granular. Renal epithelium is sometimes found, a few leucocytes, rarely a red cell, and yet many after over-exertion, etc. Uric acid and calcium oxalate crystals are common.

During acute exacerbations the urine often loses this character entirely, and it may be very difficult to distinguish the condition from acute nephritis. It is well to examine the morning and the evening urines separately, and especially after a day with a particularly hearty meal or severe exercise. During the whole course the urine in this condition resembles that found in other conditions so nearly that the clinical history and the

physical examination of the patient can not be dispensed with. The urine alone, for instance, may resemble the acute or the subacute nephritis during convalescence, waxy kidney, and the cyclic, or the so-called physiologic, albuminurias.

A division of this form into groups is exceedingly difficult; in fact, the size and color of the kidney is almost the only criterion since in nearly every case all its histologic elements are affected by degenerative, inflammatory and regenerative processes. This form of nephritis is of almost physiologic occurrence in every elderly person, the kidney becoming old with the rest of the body, and therefore slightly sclerotic. If the process, however, is simply sclerosis there should be no urinary symptoms, and hence such cases are not suspected before the autopsy. As a result of hard work, worry, various diseases as gout and lues, and certain poisons like lead and alcohol, there is degeneration of the epithelial elements and inflammation, resulting in a new growth of connective tissue, which may be general or focal, subcortical or periglomerular. The kidney becomes hard and firm, diminishes in size, and finally may be but a remnant of an organ.

In some cases contracted kidneys are found at autopsy which could not possibly have been recognized clinically from the urine. These show that a nephritis limited to foci can heal. In all such cases if it be the sclerotic process which predominates there may be practically no urinary symptoms, and at autopsy kidneys of surprisingly small size have been found. Other cases are the result of a preceding acute or subacute nephritis. The only classification which can be made, apart from the weight of the kidney and the thickness of its cortex, is according to color, hence the division into red and white kidneys, the red kidneys being the result particularly of arteriosclerosis as a primary factor. The red kidneys are large, firm, beefy, the sclerosis is considerable and yet the size of the kidney is seldom as much diminished as in the white form.

CHRONIC INDURATIVE (INTERSTITIAL) NEPHRITIS. CHRONIC DIFFUSE NEPHRITIS. WHITE KIDNEY.

Of these we have had 174 cases with autopsy. In all the following pages by weight is meant that of both kidneys.

Kidneys Over 300 Grams in Weight.—In this group are 79 cases. Of these, in 38 there was no acute renal process. The condition in some was found accidentally at autopsy on a patient dying of some other disease. The weight of these kidneys averaged 330 grams, and the cortex averaged 6 mm.

The amount of urine was practically normal, as also the specific gravity. Albumin was present in traces as a rule (26 cases). In 10 cases, however, it was present in abundance. In 5 cases on some days there would be a trace of albumin, on other days none, while in 1 case no albumin was ever found.

The casts were hyaline and granular, very rarely fatty and epithelial. In 16 cases no casts were ever found. We would emphasize the fact that 5 of these 16 were cases of carcinoma, 3 of arteriosclerosis. In 7 cases the casts were in large number. In the sediment, also, were leucocytes, epithelial cells and red blood corpuscles. In the former admissions or at the entrance to the hospital it is the rule that neither casts nor albumin were present or but a trace of albumin without casts.

In 41 cases the kidneys showed also an acute process, in some only a fatty or a parenchymatous degeneration. The average weight was 380 grams; in one case, and that

a woman, 720. The cortex averaged 7 mm. Much albumin and many casts were present in 5 cases; a trace of albumin with many casts in 2, with few casts in 14, with none in 11. No albumin but casts were found in 4, and neither albumin nor casts in 2. One of these cases is interesting, since it was of pulmonary tuberculosis with extreme parenchymatous renal degeneration; the urine of the 24 hours preceding death, however, contained neither albumin nor casts. The other was a case of septicæmia. The casts were hyaline and granular, in some epithelial, blood or pus.

In 4 cases the acute element was shown by the hemorrhages present.

There were 18 cases in which there was considerable edema and in which the symptoms of nephritis were prominent. These kidneys averaged 390 grams in weight; the cortex measured 6 mm. Here also the amount of urine was practically normal, the specific gravity rather low from 1006 to 1018. The albumin was present in a trace in 7 cases, much in 5. Casts were few as a rule, the most were hyaline and granular, but there were some fatty and waxy casts. Red blood cells, leucocytes, and epithelial cells were also present. In 7 such cases without edema, with a clinical diagnosis of nephritis, the urinary symptoms were practically the same as of those with much edema.

There were 4 cases in which the hyaline degeneration of the epithelial cells was a striking point. It is interesting to note that in one such case casts were never present, but there was much albumin. In one case there were a great many waxy casts and few other forms. In a third case there was much albumin, with granular and hyaline casts, while in a fourth there was only a trace of albumin and no casts.

Kidneys Weighing from 200 to 300 Grams.—There were 57 such cases. Among them was an interesting group of 7 cases accompanying malignant disease. The average weight of these 7 pairs of kidneys was 220 grams; the cortex averaged 6 mm. The urine, both in amount and specific gravity, was practically normal. In all these cases albumin was present if at all, in traces, and in 4 cases it was present only at times, while casts were remarkably few; in 3 cases none were found. The others showed only hyaline and granular casts. In one case, however, there were very many hyalines and granulars; in another on one occasion none, on another many granulars. In this group, therefore, the casts were absent or present in large numbers. In 2 cases with very fat cortices there were no casts.

Tuberculosis: There were six cases; the average weight of the kidney was 257 grams; cortex was 6 mm. thick. Here also only traces of albumin were present in 3, none in 2, and casts few or none. There were few casts in 1, none in 4 cases. In 1 case some time before death many casts had been found. In all only hyaline and granular casts were found.

In 18 cases the nephritis was either an accidental discovery or accompanied some more important condition. The average weight of the kidneys was 260 grams; the cortex measured 5 mm. The amount and specific gravity of the urine were practically normal. The albumin in 10 cases was present in a trace, in 5 cases in abundance, while in 3 none was found. Hyaline, granular, epithelial, pus and waxy casts were found in these cases and mixed casts were common.

In 4 cases no casts were found; in a case of hemophilia there was neither albumin nor casts; in 2 cases with very fatty kidneys much albumin and many casts were present; in another case running a slight fever

much albumin and many hyaline and granular casts were found.

In this group, further, were 25 cases with definite symptoms of nephritis. In these cases the average weight of the kidneys was about 260 grams, and the cortex measured from 4 to 5 mm. in thickness. The urine was practically normal in amount and specific gravity, although there was a tendency for the latter to be below normal. The albumin varied much, from a trace to even 0.5 per cent. and was present in all cases. The casts were of all varieties, the most hyaline and granular, in two cases there were many; waxy casts were found in 3 and epithelial in 1. As a rule, the casts were few in number; in 4 cases they were many. These cases gave a long history of nephritis. Many of these patients were in the hospital on several occasions. There was a remarkable discrepancy between the amount of albumin and the number of casts.

Kidneys of from 150 to 200 Grams in Weight.—Of these 30 cases, in 7 the average combined weight was 180 grams, and the cortex from 2 to 5 mm. The amount of urine was normal, but the specific gravity in all cases was slightly low—from 1008 to 1014. Albumin was present in traces, if at all. The casts were few in number—hyaline and granular, or none. These 7 cases were not diagnosed clinically as nephritis.

In 11 cases with edema and in 11 cases without edema the clinical diagnosis was nephritis. The weight of the kidneys averaged 180 grams. In both groups, the cortex averaged 3 mm. The amount of the urine of both groups was normal; the specific gravity low, as a rule, in some cases normal. The amount of albumin varied greatly, from a trace to 0.7 per cent. Casts were present in great variety and numbers; in some cases there were many and all forms; in some none. Red blood cells were commonly present. It should be borne in mind that all these cases mentioned with a clinical diagnosis of nephritis were acute exacerbations of a chronic form. From the urine alone, however, such a diagnosis could not be made.

In those cases with much edema the casts were abundant in 3 cases, very few in 3, while in those with little edema none were found in 5 cases and many in but one. In this latter group only hyaline and granular casts were mentioned; in the former all varieties in some case.

Kidneys Below 150 Grams in Weight.—Of these, there were 8 cases; the sum of both kidneys averaging 180 grams and the cortex measuring from 2 to 4 mm. The urine was either normal in amount or slightly diminished. The specific gravity was often low, but sometimes normal. The amount of albumin was a trace in 6 cases and a larger amount in 2. The casts were chiefly hyaline and granular, with epithelial in 3 cases and waxy in 2. In 4 cases casts were very scanty and at times not found.

Such were the terminal urinary features of cases which commonly pass as small contracted kidney and of which the classical urinary symptoms are quite different from the above. Polyuria is one of the first complaints; the patient rises at night several times to void urine of a light yellow color, with no gross sediment; the specific gravity is constantly low, varying from 1005 to 1012. Albumin is present in traces with intermissions of none for periods of from a few days to months. In the sediment very few cells and casts are found. For the latter it may be necessary to centrifugalize and to examine a large amount. The casts will be of a hyaline or finely granular nature. It is interesting to note how many of

these specimens of urine have a few red blood cells in the sediment. Functionally the kidney is almost perfect. Later, however, and this includes all the cases mentioned, the kidneys are the seat of an acute process, the amount of urine diminishes, the specific gravity rises and albumin and sediment increase so that from the urine alone one would suspect an acute exacerbation of an acute nephritis in a kidney of much greater weight than he finds at autopsy. In certain other cases, however, in which it is not the renal symptoms which predominate at death, the amount of urine may grow larger and larger until a permanent catheter is necessary, the patient dying in uremia.

In 7 of these cases hyalin was present in the capillaries. In one, with combined weight 155 grams, albumin was 0.3 per cent., casts small in number, and when present hyaline and granular. In one of 220 grams' weight the albumin was 1.2 per cent. and the casts in large numbers, hyaline, granular and especially waxy and fatty.

(To be continued.)

[THE REMAINDER OF THIS SYMPOSIUM ON NEPHRITIS, INCLUDING THE DISCUSSION, WILL BE PUBLISHED NEXT WEEK.]

A STUDY OF BRAIN INFECTIONS WITH THE PNEUMOCOCCUS.*

E. E. SOUTHARD, M.D.

Instructor in Neuropathology and Charles Eliot Ware Fellow, Harvard Medical School; Second Assistant Visiting Pathologist to the Boston City Hospital.

BOSTON.

C. W. KEENE, M.D.

Assistant in Neuropathology, Harvard Medical School.

BOSTON.

Following is a report of twelve cases of human brain infection with the pneumococcus, together with the results of inoculation of the pneumococcus in the brains of guinea-pigs. Both the human and the experimental material have been used to establish the order and time relations of the acute inflammatory changes. The work is on the lines of our study of encephalitis due to the *Staphylococcus pyogenes aureus*,¹ but was particularly suggested by the case of pneumococcus brain infection (here abstracted as Case 1) reported by Bullard and Sims² from this laboratory in 1904.

Prof. W. T. Councilman and F. B. Mallory have looked over the work. On the bacteriologic side we have been much aided by Drs. C. W. Duval and P. A. Lewis, of the hospital staff. We wish to thank Drs. J. H. McCollom, A. L. Mason, G. B. Shattuck, F. H. Williams, C. F. Withington, G. G. Sears, E. M. Holmes, and G. A. Leland for their clinical notes, and Drs. F. B. Mallory, J. H. Pratt, A. R. Diefendorf, H. C. Low, H. A. Christian, R. L. Thompson, S. B. Wollbach, C. W. Duval, P. A. Lewis, and E. B. Bigelow for their autopsy records. We are ourselves responsible for the histologic work.

CASE 1.—This was a case of severe bronchitis in a man of 50 with venereal and alcoholic history.

*Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

1. From the Pathological Laboratory of the Boston City Hospital.

2. "A Study of Acute Hemorrhagic Encephalitis (*Staphylococcus pyogenes aureus*).", E. E. Southard and C. W. Keene, Amer. Jour. of Med. Sci., March, 1905.

3. "A Case of Diffuse Encephalitis Showing the Pneumococcus," W. N. Bullard and P. R. Sims, Boston Med. and Surg. Jour., December, 1904.

Clinical Summary.—Cerebral symptoms developed after a month's illness, ushered in by increasing weakness, fever and mild delirium (symptoms on admission). Two days later there appeared flaccid paralysis of the left extremities, with some rigidity on the right, cyanosis, and incontinence. There was gradual failure, with rapid respirations, raised temperature, deepening coma, and death on the seventh day.

Anatomic Summary.—There was acute purulent bronchitis with edema, softening and punctiform hemorrhage involving the greater part of the right cerebral projection system with foci in the left centrum semiovale.

Microscopic Findings.—There were pneumococcus septicæmia, slight arteriosclerosis affecting all the organs, acute bronchopneumonia, extensive diffuse encephalitis with hemorrhages and cellular lesions related to the cortical vascular system and confined to the subcortical region. The lesions consisted of accumulations within and surrounding the adventitia of large numbers of mononuclear cells (granule cells), and small numbers of lymphoid and plasma cells, with a few polymuclear neutrophilic cells and a few eosinophiles.

There were solution and fatty change of the myelin in the surrounding tissue, and hyperplasia and proliferation of neuroglia cells with formation of numerous astrocytes. There were edema changes in the nerve cells of the cortex, fatty changes in the cord, and early central chromatolysis of the anterior horn cells.

Lanceolate diplococci were present in cultures and were found in and surrounding the cells of the exudate in the lung lesions and in the tissue and granule cells of the brain.

CASE 2.—J. H., a boy of 10, was admitted to Dr. J. H. McCollom's service at the south department of the Boston City Hospital, July 13, 1898.

History.—He had measles and whooping cough at 5 months at 8 years of age. He was well the day before entrance. He ate a heavy lunch before bedtime, and had headache and vomiting during the night. He "slept" till next afternoon, when respirations became stertorous. The boy was admitted to the hospital in coma, with stertorous and labored breathing, profuse nasal discharge, dilated pupils not reacting to light, rales throughout the chest, small, high tension, rapid pulse, tense and prominent abdomen, exaggerated patellar and plantar reflexes, anesthesia of extremities and marked muscular susceptibility to pain. He was catheterized and the urine showed a large trace of albumin. The coma continued. The patient vomited twice. Death occurred about one hour after midnight.

Clinical Summary.—A boy of 10 goes to bed one evening after a heavy lunch, vomits and has headache in the night, sleeps all day, is admitted to hospital in coma and dies twelve hours later, less than twenty-eight hours after the onset of the symptoms.

Anatomic Findings.—The autopsy, performed by Dr. F. B. Mallory, July 14, 1898, showed: Pia injected and edematous; no increase of fluid in ventricles. Small areas of hemorrhage and beginning softening were found in the cerebral cortex beneath the olfactory lobes, along the inner side of the right temporal lobe, and in the right side of the pons. No area exceeded 1 cm. in diameter.

Anatomic Diagnoses.—Pneumonia in middle lobe of right lung and base of left lower lobe. Petechial hemorrhages in skin over chest. Hemorrhages in mucous membrane of bladder. Hemorrhages in cerebral cortex.

Microscopic Findings.—Cultures from the brain and kidney showed a variety of organisms, including the pneumococcus: from lung, pneumococcus; from heart's blood, liver and spleen, sterile.

The pia mater over the areas of softening showed considerable edema, with polymuclear leucocytes and mononuclear cells in about equal numbers. Leucocytes wandered freely through the cerebral tissue. The subpial layer of neuroglia was thin. The areas of softening consisted of small hemorrhages, with polymuclear leucocytes, some of which contained numerous lanceolate diplococci. In some cases the free blood was confined to the adventitial clefts. Lesions of the arteries were rare. The walls of the small veins were sometimes obscured by masses of leucocytes; but there was no thrombosis or lifting of endothelium by exudate.

CASE 3.—W. B., a man of 70, was admitted to Dr. G. G. Sears' service at the Boston City Hospital, Sept. 26, 1898.

History.—Three or more days before admission his face had begun to swell, burn and itch, and the lids swelled so that he could not see. Temperature was 101 F. He was slightly delirious, but could be aroused to complain of swelling ankles, shortness of breath, palpitation and dizziness. He was said to have had "shocks" eight years and one year ago. Thorax, abdomen and extremities were negative. The urine showed a trace of albumin and numerous fine granular casts, with a few cellular elements. The patient died four days later. He fell out of bed during delirium the night of entrance and cut a gash in the left occiput. The delirium continued. Three days after entrance the temperature began to rise and the pulse to fail, the respirations became stertorous. Death followed the next morning.

Clinical Summary.—Man of 70, with heart symptoms and kidney disease and a history of paralytic shocks, dies in delirium a week or more after the onset of facial erysipelas.

Anatomic Findings.—The autopsy, performed by Dr. J. H. Pratt, Sept. 30, 1898, showed:

Dura distended over cortex and convolutions flattened. Beneath the dura over the left parietal lobe there was a thin layer of coagulated blood. On the cortex beneath the arachnoid were scattered areas of greenish purulent exudate, especially marked over the frontal lobes, and also over the cerebellum. The base was not involved. The ventricles were dilated, and contained a small amount of clear serous fluid. The walls were not softened.

Anatomic Diagnoses.—Acute purulent meningitis. Old tuberculous focus in lung. Edema and congestion of lungs. Acute bronchitis. Chronic obliterative appendicitis. Chronic interstitial nephritis. Coronary endarteritis. General arteriosclerosis. Chronic interstitial orchitis.

Microscopic Findings.—Cultures from heart's blood, liver, meninges and lateral ventricles showed pneumococcus. Spleen and kidneys were sterile. Sections of cortex presented a constant picture. The exudate consisted of polynuclear leucocytes and mononuclear cells (proportion between 5 and 10 to 1) free in the pial spaces. A few spaces in the middle zone of the pia contained only granular coagulum. Much round-meshed fibrin was deposited in small foci about the small veins and along the inner zone of the pia. The elastica of the small arteries was penetrated by the polynuclear cells, which lay in spaces beneath the endothelium (or in clefts of the elastica) together with mononuclear cells.

The layer of subpial glia was dense and fine-meshed. Eccentrically swollen glia cells, with a small number of embracing fibrils, were frequent. There were a few polynuclear leucocytes in the nerve-cell layers, as a rule near capillaries.

CASE 4.—T. W., a man of 44, was admitted to Dr. G. B. Shattuck's service at the Boston City Hospital Oct. 29, 1898.

History.—He had breakbone fever in Baltimore at the age of 19. Right chest was tapped for pleurisy one year before entrance. There was severe pain in the lower left chest four days before entrance. There were cough, orthopnea, insomnia and sweating. At entrance there were signs of effusion in the left chest; there were two dry taps. About twelve days after admission, the patient began to have severe cough and irregular temperature, with persistence of signs in chest and increasing pallor. Two days later he complained of pains in the eyes and severe headache and became semicomatose. The area of bronchial breathing increased. A friction-like murmur developed in the lower heart area. Death occurred November 14, without recovery from coma.

Clinical Summary.—Man of 44, with history of pleurisy of a year's standing, develops a fresh attack, in the course of which, sixteen days after onset, twelve days after admission to hospital, he became much worse. There were pains in the eyes, headache, coma. Death occurred three weeks after onset of symptoms and four days after exacerbation of symptoms.

Anatomic Findings.—The autopsy, performed by Drs. J. H. Pratt and Dieffenendorf, Nov. 14, 1898, three hours after death, showed:

Head (Dr. Dieffenendorf): Pia showed over vertex and base a slight haziness, and along longitudinal fissure on both hemispheres, several areas from 1 to 3 cm. in diameter, greenish

yellow in color, on section showing thickness of from 1 to 4 mm., not exuding but rather firm. A few similar areas were scattered in the sulci over the frontal and parietal lobes. A similar but more extensive exudate was found in the interpeduncular space, along the ventral surface of pons and medulla, and at the lateral margins of cerebellum.

Brain tissue was firm. On section a greenish yellow exudate was found in the posterior horns of the lateral ventricles, and in the floor of the third ventricle. Ependyma elsewhere was clear. Vessels at base were negative. Middle ears were normal.

Cord: On puncture of the dura of the lumbar cord there escaped a clear fluid with several patches of greenish yellow color. This exudate was found along the entire extent of the cord on the right posterior aspect, mostly in flakes, but in places as a rather thick layer, 1x2 cm. in breadth and length, and 5 mm. in thickness.

Anatomic Diagnoses.—Acute purulent cerebrospinal meningitis. Fibrinopurulent encysted pleurisy. Serofibrinous pericarditis. Chronic verrucose endocarditis. Old fibrous obliterative pleurisy. Hydrocele. Parenchymatous degeneration of liver and kidney. Fatty degeneration of kidney. Fatty degeneration of aorta. Acute fibrinopurulent mediastinitis.

Microscopic Findings.—Cultures from heart's blood, pericardium, pleura and meninges, showed pneumococcus. Spleen and liver gave *B. coli*; kidney was negative.

The meningeal exudate varied in different places in the proportion of polynuclear leucocytes to mononuclear cells. Everywhere there were more mononuclear cells than leucocytes. In the wide sulcal space the chief cell found was the phagocyte laden with polynuclear leucocytes. There was little fibrin except near the veins. Vascular lesions were not prominent over the cerebrum and cerebellum, but lifting of endothelium by exudative cells was found in the small vessels of the spinal pia mater.

The subpial glia was coarse, even and regular. Behind the fibrillar layer were numerous eccentrically swollen glia cells, often with two or even three nuclei. Some of these cells showed fibrillae in close apposition to processes. Leucocytes penetrated the cortex somewhat freely and occurred singly in the deeper nerve-cell layers.

CASE 5.—R. A., a man of 35, was admitted to Dr. A. L. Mason's service at the Boston City Hospital, April 15, 1900.

History.—Chills and cough with yellowish-white sputum had set in six days before entrance. There were pain in the right chest, rise of temperature and free perspiration. He had been in bed four days. He was admitted in delirium, with rusty sputum and with signs of pneumonia in the right chest. Knee jerks and plantar reflexes were normal. There was inflammation of the skin about the shoulders. On April 17 the right forefinger became inflamed and the swelling spread to the dorsum of the hand. An incision was made and pus withdrawn. By April 22, the morning temperature had become normal, but began to rise again irregularly. On the afternoon of April 25 the patient suddenly became much worse, coughed spasmodically and showed dyspnea, cyanosis and delirium. There was stiffness of the neck without retraction. Meantime the inflammation in the hand had largely subsided. The next day Cheyne-Stokes respiration set in, the pupils dilated, the knee jerks became slight and the plantar reflex was lost on the right side. Death occurred in less than twenty-four hours after exacerbation of the symptoms.

Clinical Summary.—Man of 35, with history of excess in alcohol, shows signs of pneumonia in the right chest. Two days after admission (eight days after onset of symptoms) inflammation of right forefinger and hand set in. Incisions were made to relieve the swelling and were followed by general improvement. Sixteen days after onset of symptoms and ten days after admission, a sudden relapse occurred, with spasmodic cough, stiffness of neck and delirium. Death occurred the next day.

Anatomic Findings.—The autopsy, performed by Dr. H. C. Low April 27, 1900, showed:

No congestion of the dura which was not adherent or thickened. The sinuses were distended by fluid blood. The pia was rather opaque, and between it and the brain a greenish-yellow material, thick and viscid in appearance, was visible.

The veins were very much congested. This appearance was most pronounced on either side of the median line, decreasing toward the sides and on the inner surface of the frontal lobes, where it was marked only along the course of the vessels. The vessels at the base were congested and the entire cerebellum was covered by the exudation. The ventricles did not contain an excess of fluid, but the fluid in the lateral ventricles was slightly opaque. Middle ears were normal.

Anatomic Diagnoses.—Acute purulent meningitis. Acute pericarditis. Acute splenitis. Organizing lobar pneumonia. Acute endocarditis (aortic). Septic wound of hand. Ascites. Acute fibrinous pleurisy. Acute bronchitis.

Microscopic Findings.—Cultures from heart's blood, left lateral ventricle and lungs, showed pneumococcus. The right lung showed streptococcus. Spleen, liver, gall bladder and kidney were sterile. The picture varied in different parts of the pia mater. The zone adjacent to the nerve tissue, the perivascular region and certain spaces in the middle third of the pia mater contained much fibrin and polynuclear leucocytes which far outnumbered the mononuclear cells. In the wide sulcal space the mononuclear cells equalled or excelled the leucocytes in number. The large sulcal veins showed infiltration of the intima, with polynuclear leucocytes and extensive increase in the intimal cells. The subpial glia was scanty. A few glia cells with two nuclei occurred; there was no increase in fibrils. Polynuclear leucocytes were found about the small vessels, singly free in the cortex, but seldom in the underlying white matter.

CASE 6.—J. H., a man of 47, a teamster and a drunkard, was admitted to Dr. G. G. Sears' service at the Boston City Hospital, Jan. 6, 1901.

History.—Four days before entrance to hospital he fell on his back, but was able to move about afterward, though drunk. He took to bed for a short while. He complained two days before entrance of pain in the head and back of the neck. He ate nothing for twenty-four hours before entrance. At entrance there was delirium, restlessness and tremor of extended fingers. Pupils were equal, with normal light reaction. Knee jerks were lively. The urine showed .25 albumin and many (chiefly granular and epithelial) casts. Physical examination was chiefly negative. The next day deep coma had set in and death occurred January 8.

Clinical Summary.—Man of 47, dies in coma seven days after a fall.

Anatomic Findings.—The autopsy, performed by Dr. H. A. Christian, Jan. 9, 1901, showed:

Head: Dura is very tense. When opened there was a gush of grayish turbid fluid, and the dura collapsed to a considerable extent. The surface of the cerebrum and cerebellum was covered with greenish-yellow pus and fibrin. This was everywhere most marked along the course of the larger blood vessels, which appeared as dark red stripes bordered with greenish yellow. It was most prominent over the vertex of the cerebrum, along the Sylvian fissure, over the superior surface of the cerebellum and at the base in the area bounded by the circle of Willis, and along the olfactory nerves. The exudate was less abundant at the base than at the vertex. Over the convolutions where the exudate was thin, many small injected blood vessels could be seen. The superior longitudinal, lateral and superior and inferior petrosal sinuses contained fluid blood and were normal.

Smears from the exudate showed pus cells and many diplococci, some lanceolate, and a few large bacilli. Many of these were within the pus cells. The diplococci failed to show definite capsules when stained by Welch's method, though they were indicated in some places. The organisms stained by Gram's method. The middle ears were normal.

Spinal cord: Dura was normal, but distended. Over the posterior surface of the cord there was much yellowish pus and fibrin similar to that on the surface of the brain. Over the posterior surface of the cord the long spinal vessels were much distended, appearing as small sinuous red cords.

Anatomic Diagnoses.—Chronic fibrinous pleuritis. Chronic fibrinous pericarditis (milk patches). Hypertrophy and dilatation of heart. Fatty degeneration of heart. One accessory coronary artery. Congestion and edema of lungs. Chronic passive congestion of liver. Acute nephritis. Hydrocele and vari-

cocele. Slight chronic aortitis. Fatty degeneration of skeletal muscles. Acute cerebrospinal leptomenigitis.

Microscopic Findings.—Cultures from pia mater gave pneumococcus pure. The kidney gave pneumococcus and *Staphylococcus pyogenes aureus*. The lung contained streptococcus, *Staphylococcus aureus* and *B. protus*. Liver and spleen were sterile. The meningeal exudate was evenly cellular, except about the veins near the nerve tissue where fibrin was developed. The cells were almost all polynuclear leucocytes. In the adventitia of the veins, however, the proportion of mononuclear cells rose to 1 in 10 or 20. In the veins there were numerous minute mural thrombi, largely covered in by endothelium. The subpial glia was thin, but close-meshed. The outer layers of cortex contained numerous neuroglia fibrils of fine, even diameter. There were a few free leucocytes in the outer layers, caught singly sometimes in amoeboid shapes. Mitoses regarded as in neuroglia cells occurred in the subpial layer internal to the dense sheet of fibrillae, also occasionally in the layer of small pyramids. The nerve cells were pigmented. Cells occupying the site of satellite cells were caught in mitosis in several places; but in general there was slight evidence of increase in number of these cells.

CASE 7.—W. N., a man of 58, was admitted to Dr. F. H. Williams' service at the Boston City Hospital, Jan. 21, 1901.

History.—He had had cough and expectoration six or seven weeks before entrance. Chills and backache set in 6 days before entrance. He had had headache for 4 days before entrance. At entrance there were shooting pains in various parts of the body, skin and sclerae were a little yellow, and ears and lips a little cyanotic. The pupils were small and slightly irregular, reacting sluggishly to light. There was radial arteriosclerosis. Emphysema was present and râles more marked at right base; there were also an area of dulness, increased fremitus, and bronchial breathing at the right base. The abdomen was rigid and tympanitic. The knee jerks and plantar reflexes were normal. The discomfort from the pain in the side, distension of abdomen, and frequent catheterization persisted till January 24, when late in the evening the pulse became thready, respiration labored, and the skin cyanotic. Death occurred five hours later, January 25.

Clinical Summary.—Man of 58, arteriosclerotic, with history of six or seven weeks' bronchitis, and less than a week of chills, backache and headache, dies three days after entrance in the course of pneumonia of the right side.

Anatomic Findings.—The autopsy, performed by Dr. H. A. Christian, Jan. 26, 1901, showed:

Head: Superior longitudinal sinuses were normal. The surface of the cerebrum and cerebellum was greenish, opaque and gelatinous, and dotted with numerous whitish areas about 1 mm. in diameter. The pia was thickened everywhere over the upper surface and tore with some difficulty. Smears made from under surface of the pia showed many pus cells and Gram staining diplococci. Many of the diplococci were lanceolate and when stained by Welch's method showed fairly distinct capsules. The ventricles contained a small amount of normal fluid. The brain substance appeared normal. The middle ears were normal.

Anatomic Diagnoses.—Acute leptomenigitis. Jaundice (universal). Chronic fibrinous pleuritis. Acute serofibrinous pleuritis. Fatty degeneration and brown atrophy of heart. Lobar pneumonia. Acute bronchitis. Acute degeneration of kidney. Slight chronic aortitis.

Microscopic Findings.—Cultures from the under surface of pia mater, lung, liver and kidney showed pneumococcus. The meninges were wide, but contained few exudative cells except in the inner zone and about the veins. In both regions the mononuclear cells surpassed the polynuclear leucocytes in number. In the inner zone of the pia there was considerable fibrin inclosing leucocytes, many of which stain poorly. The mononuclear cells in the adventitia of the veins frequently had nuclei indented on one side. The intimal cells of the arteries and veins were swollen and increased in number. An occasional arteriole had its lumen seven-eighths narrowed by swollen intimal cells.

The subpial layer showed a thin, dense sheet of neuroglia. The cortex showed numerous fibrils as far inward as the outer limits of the layer of large pyramidal cells. Scattered through

the cortex were neuroglia cells containing pigment. There was a slight increase of glia fibrils in parts of the underlying white matter. The neuroglia cells failed to show acute changes. The vessels of the cortex were engorged with blood. In their sheaths were a few mononuclear cells, but seldom a polynuclear leucocyte. The nerve cells stained well, were often overpigmented, and were attended by numerous satellite cells, some of which showed a tendency to be metachromatic.

CASE 8.—W. M., a man of 37, was admitted to Dr. C. F. Withington's service at the Boston City Hospital, Feb. 26, 1903.

History.—He had had chills, fever, pain in left chest, cough, and dark expectoration for a week before entrance. There were pneumonia and pleurisy on the left side. Pupils were normal. Knee jerks were normal. The plantar reflexes were exaggerated. The urine showed a few hyaline casts. Death occurred the day after entrance.

Clinical Summary.—Man of 37, with history of "bronchitis" for years, dies one day after entrance to hospital, eight days after onset of symptoms of pneumonia of left side.

Anatomic Findings.—The autopsy, performed by Dr. E. E. Southard, Feb. 28, 1903, showed:

Head: Dura was tense and of normal color. Arachnoidal villi were moderately developed. The pia was of a green-gray color, more marked over the frontoparietal and cerebellar regions and at the base. The greenish color in places was obscured by edema, which in the parietal and occipital regions was marked. There were pneumococci in the smear from the exudate. The convolutions were not markedly flattened. The ventricles were normal and contained a normal amount of fluid. Substance in the gross was normal. The sinuses contained fluid blood and long shreds of chicken-fat clot. The middle ears were normal.

Anatomic Diagnoses.—Lobar pneumonia (gray hepatization). Acute leptomenigitis. Acute fibrinopurulent pericarditis. Chronic adhesive pleuritis. Chronic adhesive pericarditis. General arteriosclerosis.

Microscopic Findings.—Cultures from heart's blood, lung, spleen and brain showed pneumococcus. The exudate in the pia mater was chiefly cellular, but in certain wide spaces in the middle zone it consisted of a granular coagulum. About the small veins and along the inner zone considerable fibrin was developed. The cells were mainly polynuclear leucocytes; but mononuclear cells occurred in the proportion of 1 to 10 or 20, or in a lesser proportion. The small veins showed an increase of intimal cells in compact layers penetrated by polynuclear leucocytes. The small arteries had their intima lifted by polynuclear leucocytes and mononuclear cells. The subpial layer showed considerable neuroglia in a loose sheet, which in places was made looser by edema. A few polynuclear leucocytes were found free in the outer portion of the layer of small pyramids. It was easy to mistake altered neuroglia cells of the edematous outer layers for polynuclear leucocytes. Pigmented neuroglia cells and considerable numbers of satellite cells occurred.

CASE 9.—G. G., a man of 25, was admitted to Dr. C. F. Withington's service at the Boston City Hospital, May 25, 1901.

History.—He had received a head injury on board ship. He lay unconscious for some time in a hospital in Porto Rico, but recovered. He had headache for four days previous to entrance, and there was unconsciousness for two days. On entrance he was restless and cried out when touched. He lay on his side, with the legs drawn up. His neck was stiff and retracted. Passive flexion was painful. The abdomen was slightly retracted. The knee jerks and plantar reflexes were exaggerated. Kernig's sign and Babinski's sign were present on both sides. There was *tache cerebrale*. There was incontinence of feces, and the restless delirium persisted. Two days after entrance the pupils began to react sluggishly to light, and two days later the head was retracted to the left, with conjugate deviation of the eyes to the left. The extremities were somewhat spastic. Kernig's sign became less marked, and Babinski's sign was lost. Death occurred five days after entrance.

Clinical Summary.—Man of 25, with obscure history of previous head injury, has headache four days and is unconscious two days before entrance. Death occurs six days later, 10 days from onset of symptoms of meningitis.

Anatomic Findings.—The autopsy was performed by Drs. R. L. Thompson and E. E. Southard 32 hours after death.

Head: The scalp and cranium were normal. The sphenoidal sinus contained a small amount of clear gelatinous material. The other sinuses were normal. The middle ears were normal. The right cavity contained a little clear gelatinous material resembling that in the sphenoidal sinus. The pores of the right cribiform plate contained fibrinous pus in continuity with the exudate about the right olfactory lobe. The nasal cavities were clean.

Brain: Weight, 1,350 gms. The dura was slightly thickened, clung lightly to pia on peeling, but there were no adhesions. The sinuses of the dura contained cruor clot. The pia was tense, injected and a little sticky. The tissues about a few large sulcal veins were infiltrated with greenish, stringy pus. The frankly purulent areas of the vertex were never over 2 cm. in diameter and lay at varying distances within 6 cm. therefrom. There were a few subpial collections of pus over the cerebellum, especially near the brachium. A few of the arachnoidal villi were injected and a little more plastic than usual. The tissues about the basal veins, the chiasm and the infundibulum showed a deep layer of moist, stringy, greenish pus, apparently all within the pia. Both Sylvian fissures showed an extension of the exudate for 3 cm. The gyri were flattened, firm, a little plastic, of homogeneous consistence and slightly pinker than usual. The cortical markings were everywhere distinct. Substance clung to the knife on section. The puncta cruenta in various places in the white matter were unusually distinct; and, opposite the left frontal cortex, there were numerous punctiform hemorrhages in very clinging edematous substance. In the middle of this area was a focus 1 cm. in diameter composed of greenish fibrinous pus surrounded by a ragged injected wall. The right olfactory lobe was yellow and softer than the left and was glued in an exudate continuous with the exudate at the base. All the ventricles contained greenish fluid containing fibrin and grumous coagulum. There was no normal ependyma remaining. The exudate could be removed only by scraping and extends for from 1 to 2 mm. into subependymal tissue. The floors of the lateral and fourth ventricles looked like the walls of abscess cavities. The medulla was buried in pus filling the pial meshes. The substance was a little softened and over injected.

Cord: The dura was thick, a little brawny, and internally roughened. It peeled from the pia with slight difficulty. The meshes of the pia were distended with pus resembling that found in the cranium. The outermost layers of the pia were rather edematous, which made the exudate look more glassy than the cranial exudate. On section the cord appeared moister than normal and the pial vessels were markedly injected, resembling in places so many red spokes let in from the pial rim. The larger veins were not much injected. The exudate in places, notably about the cauda equina, was very thick and with the included nerves might measure from 0.75 to 1 cm.

Anatomic Diagnoses.—There were edema and congestion of the lungs, edema of the kidneys and acute splenitis. There was cerebrospinal meningitis, with focal abscess, encephalitis and cerebriphalus. There was an exudate about the degenerating right olfactory lobe, with slight inflammatory reaction by extension in the cerebral and spinal dura.

Microscopic Findings.—Cultures from heart's blood and brain gave pneumococcus; from right lung, staphylococci; from left lung, *Streptococcus pyogenes*; from liver, *B. coli*, *B. proteus*, etc.; from spleen, *B. coli*. Cultures from the kidney were sterile. The meningeal exudate was largely cellular. The centers of the clefts were occupied by polynuclear leucocytes and an equal number of mononuclear cells. Near the vessels the mononuclear cells were more frequent and were often vacuolated or phagocytic for polynuclear leucocytes. Fibrin occurred in masses of irregular distribution, as well as about the veins. The arteries showed a minor degree of intimal swelling, with occasional included cells. The subpial neuroglia showed numerous swollen cells and a few mitoses. There was an increase of fibrils in the subpial layer. The cerebellum of this case showed an exudate much richer in large leucocyte-containing phagocytes than the cerebral exudate, and neuroglia-cell mitoses were fairly frequent in the molecular layer. Polynuclear leucocytes wandered freely in the cortex.

CASE 10.—E. V., a man of 48, was admitted to Dr. C. F. Withington's service at the Boston City Hospital, Feb. 17, 1905.

History.—There was a history of excess in alcohol. He had rheumatism 5 years before entrance. Two days before entrance he parted from a friend at 10:55 p. m., intoxicated but without symptoms of illness. At 11:10 p. m. the man was brought to the relief station with a story of a fall and injury to the head. He was discharged as well the next morning. He was dazed on reaching home, and had pain on the right side of the head. Delirium set in at 10 p. m. February 16. On entrance respiration was rapid and noisy. There was ecchymosis about the left eye. Râles were more marked and respiration more marked in the right back; pulse was rapid and knee jerks equal; Kernig's sign and Babinski's sign were absent. Leucocytosis was 32,600. The delirium continued. By 9:30 the next evening right hemiplegia had developed, with Kernig's sign and Babinski's sign. Death occurred 11 hours later.

Clinical Summary.—Man of 48, alcoholic, was brought to Relief Hospital one night with contusion of face and discharged next morning. He was dazed next day, and delirium was present in the evening. He entered hospital with signs in right lung; hemiplegia occurred on evening of second day, about 70 hours after original trouble. Death occurred eleven and one-fourth hours later.

Anatomic Findings.—The autopsy was performed by Drs. E. B. Bigelow and P. A. Lewis 23 hours after death and showed:

Head.—The scalp was rather thick and loose, with a moderate amount of fluid blood beneath the lateral portions, particularly on the left. The calvarium was thick and moderately dense; the dura mater was loose. Convolutions could not be made out through the membranes. Everywhere beneath the dura and still more beneath the pia mater there was an abundance of yellow, tenacious, fibrinopurulent exudate. The distribution was quite even, although there was slightly more over the vertex than at the base. The ventricles contained a considerable amount of clear fluid, with a flocculent yellow precipitate. Section showed a firm, moist surface; the color was rather a dull pinkish-white. The puncta cruenta were well marked. The exudate extended along the trunk of the cranial nerves for a moderate distance. The Gasserian ganglia were infiltrated with pus. The middle ears were normal, and the upper nasal passages seemed normal.

The spinal canal contained a considerable amount of fibrinopurulent fluid. The cord was firm. The vessels were injected.

Anatomic Diagnoses.—Bronchopneumonia. Nephritis. Arteriosclerosis. Cirrhosis of liver. Old infarct of spleen. Acute cerebrospinal meningitis.

Microscopic Findings.—Cultures from heart's blood, spleen and brain were sterile. One culture from lateral ventricle was contaminated with *Staphylococcus albus*. Drs. Duval and Lewis were able to recover the pneumococcus from a rabbit into which pus from the ventricle was injected. The meningeal exudate was composed largely of cells; the polynuclear leucocytes slightly outnumbered the mononuclear cells. Fibrin occurred about the small veins. The endothelium of some arteries was lifted by a deposit of cells, chiefly polynuclear leucocytes. The subpial neuroglia was fairly dense but edematous. There was no evidence of acute neuroglia cell changes.

CASE 11.—J. M., a boy of 10, was admitted to the aural service of Dr. E. M. Holmes at the Boston City Hospital Sept. 27, 1904.

History.—Two weeks before he was seen in the outpatient department with bilateral otitis media. A right mastoid operation was performed September 29 by Dr. Holmes, but was stopped on account of hemorrhage. The temperature remained high. The patient vomited sometimes after eating. Two weeks after entrance a second mastoid operation was done on the left side by Dr. G. A. Leland. After this the temperature fell, but five days later right facial paralysis developed with well-marked risus sardonius on left. There were ptosis of the left eyelid, slight horizontal nystagmus, convergent strabismus on right, slight rigidity of neck, and Kernig's sign. Toward evening, twitchings of the left side of the face developed and the paralysis gradually disappeared. Death occurred the next day.

Clinical Summary.—Boy of 10, with bilateral otitis media of unknown duration (over two weeks), on whom mastoid operations were performed, death occurring three weeks after admission and one week after a second operation.

Anatomic Findings.—The autopsy was performed by Dr. C. W. Duval 27 hours after death and showed:

Head.—The scalp and calvarium were normal. Behind the left ear was a surgical incision 5 cm. in length, running parallel with the external ear and directly over McEwen's triangle. Six or eight stitches held it together. The dura was normal, adherent except along petrous portion of the left temporal bone. The sinuses contained fluid blood. The whole of the left hemisphere beneath the pia was covered with thick, greenish-yellow pus. Parts of the cortex beneath this pus showed marked depressions. The right hemisphere was congested, and the convolutions and sulci obliterated. The cortical substance was quite firm in consistence.

Anatomic Diagnoses.—Chronic pachymeningitis. Purulent leptomenigitis. Acute encephalitis. Mastoiditis (acute and chronic). Edema and congestion of the brain. Chronic pericarditis.

Microscopic Findings.—Cultures from heart's blood, liver, spleen and meninges were sterile. Numerous Gram-staining, lancet-shaped diplococci with capsules were found in smears from meninges. The microscopic picture in the cortex was mixed. There was an exudate of small mononuclear cells, some of them lymphocytes, about some veins. Besides this, there was a deep layer of fibrin with polynuclear leucocytes emeshed, and there were foci composed chiefly of polynuclear leucocytes. A great portion of the acute exudate failed to stain well. Vacuolated and leucocyte-containing mononuclear cells were frequent. The small arteries showed swelling without proliferation of endothelium. The subpial neuroglia showed mitoses and eccentrically swollen cells. There were a few newly-formed fibrils. Leucocytes did not wander freely into the nerve substance.

CASE 12.—J. M., a woman of 45, entered the aural service of Dr. G. A. Leland, April 18, 1905.

History.—She had had pain in the right ear for three weeks. The evening before entrance coma set in. At entrance there was prostration. Temperature was 102.6; respiration, 50; pulse, 120. The right pupil was larger than the left; both pupils were sluggish to light. The retina were congested and there was paralysis of the right sixth and seventh nerves. There were diminished sensation of right side of body, stiffness of neck with pain on pressure, absence of knee jerks, a suspicion of Kernig's sign on both sides and mastoid tenderness. A mastoid operation was done at midnight. Death occurred 10 hours later.

Clinical Summary.—A woman of 45, with history of pain in right ear for three weeks, becomes comatose and shows sensory and motor paralyses of right side of body. Death occurred 10 hours after mastoid exploration.

Anatomic Findings.—The autopsy was performed by Dr. S. B. Wolbach 1 hour after death and was limited to the head.

There was a wound of right mastoid operation. The subcutaneous tissue of the scalp was slightly edematous. The calvarium was of average thickness and density. The dura was normal. The right superior longitudinal, the occipital, superior and inferior petrosal sinuses and right lateral sinus were normal and contained liquid blood and cruor clot. In the left lateral sinus at the torular Herophili there was a thrombus beginning at the junction of the right and left lateral sinuses and extending laterally to the left for a distance of 1 cm. This thrombus was grayish-pink in color, friable and firmly attached to the walls of the sinuses. Close to the jugular foramen, and 6 cm. from the torular, there was another similar thrombus 1.5 cm. in length. Between the dura and the temporal bone there was a thin layer of clotted blood covering an area about 7 cm. in diameter. Along the course of the vessels of both hemispheres there was a grayish-yellow exudate, thickest at the fissure of Sylvius and diminishing toward the median fissure. This exudate was subpial, approximately equal in amount on both sides and extended to the median fissure on both sides. The base of the brain was covered with a similar, rather more abundant deposit, thickest at the be-

gining of the fissures of Sylvius about the infundibuliform process and third nerve. The entire surface of the cerebellum was covered with a similar exudate. The consistency of the brain seemed good, and it cut with ease. The cut surfaces were rather moist; puncta cruenta were prominent as oozing points. Each ventricle contained about 5 c.c. of yellowish, cloudy liquid. At each posterior horn and at each lateral horn there was a small quantity of thick, greenish-yellow puriform matter. The pineal body was represented by a cyst 1 cm. in diameter. The exudate on the surface of the cerebellum and geniculate bodies was continuous beneath the splenium with a similar exudate present in the velum interpositum about the pineal body. Section of the basal and centrum semiovale showed nothing abnormal. The pons and medulla were normal. The exudate extended downward from the pons, medulla and cord as far as could be seen through the foramen magnum. The left middle ear was normal. In the right middle ear, the upper anterior half of the membrane tympani was destroyed. The cavities of the middle ear and antrum were filled with yellowish-red granulations. The incus lay free in the cavity of the middle ear. The malleus was held loosely in position. The cells of the surrounding cancellous bone contained a thick, clear, yellowish fluid. The sphenoidal sinus contained a quantity of gelatinous, yellowish material. Cover-glass preparations from the exudate at the base of the brain and from that in the ventricles showed many lanceolated, Gram-staining diplococci.

Anatomic Diagnoses.—Pneumococcus meningitis. Thrombosis of left lateral sinus. Chronic otitis media. Infection of sphenoidal sinus. Mastoid operation.

Microscopic Findings.—Cultures from the meninges showed pneumococcus. The meningeal exudate varied. In some places polymuclear leucocytes surpassed the mononuclear elements in number, but in most places mononuclear cells, chiefly phagocytic for polymuclear leucocytes, occurred in large numbers. Proliferation of the intima and infiltration of the walls of the veins and exudative lifting of the arterial intima were found. Occasionally a small vein was found completely occluded by a fresh leucocytic thrombus. The subpial neuroglia was fairly dense. Polymuclear leucocytes were sometimes found in the cortex and wandering freely in subependymal tissues.

GENERAL CLINICAL SUMMARY.

Eleven patients were male, one (Case 12) female. The youngest were two boys of 10 (Cases 2 and 11), the oldest a man of 70 (Case 3). The average age was 43. Seven patients were between 35 and 50, 3 under 35, two over 50.

Two cases followed inflammation of the middle ear (Cases 11 and 12). The other ten cases showed no inflammation of the middle ear.

Two (Cases 6 and 10) gave a history of trauma while drunk. The patient in Case 9 is said to have recovered from head injuries.

Four cases gave history of excess in alcohol (Cases 1, 5, 6 and 10).

Four cases gave history of pyogenic infections of long standing, three (Cases 1, 7, 8) of chronic bronchitis, one (Case 4) of old pleurisy.

The character of onset varies. Cases 11 and 12 were the outcome of neglected otitis media. In cases 6 and 10 the onset was probably rapid, but obscured by alcoholism. Cases 7 and 8 were incidents of pneumonia. Case 5 of unresolved pneumonia, Case 4 of pleurisy, Case 3 of erysipelas. Case 2 was fulminant.

The durations of the acute symptoms and of the symptoms ascribable to cerebral lesions may be assigned (subject to the usual reservations) as given in the accompanying table.

The cases may be characterized briefly as follows:

Cases 11 and 12 were clinically clear: otitis media and sequelae. Of the other cases, 1, 2, 9, 10 and per-

haps 6 could be regarded in life as showing cerebral symptoms, and Cases 4 and 5 gave somewhat doubtful evidence in life of the lesions afterward discovered. Cases 7 and 8 could scarcely be more definitely labeled than as cases of severe pneumonia. Case 3 was apparently not more than a septicemia.

Duration of acute symptoms.	Duration of cerebral symptoms.
Case 1.—5 weeks.....1 week.
Case 2.—28 hours.....28 hours.
Case 3.—1 week.....1 week.
Case 4.—3 weeks.....4 days.
Case 5.—17 days.....1 day.
Case 6.—1 week.....1 week.
Case 7.—7 to 8 weeks.....	pneumonia, 10 days.
Case 8.—8 days.....	pneumonia, 8 days.
Case 9.—10 days.....10 days.
Case 10.—81 hours.....11 hours.
Case 11.—Over 5 weeks.....1 day.
Case 12.—Over 3 weeks.....1 day.

GENERAL ANATOMIC SUMMARY.

The brain lesions varied in character and distribution. The lesions affected meninges, ventricles, or the nerve tissue itself.

Meningeal lesions were found in all cases except 1 and 2. The meningeal exudate was greenish or yellowish and contained, as a rule, much fibrin. The exudate was always deeper in the sulci and could be found there in discontinuous sheets. The upper surface of the cerebrum (especially along the vertex and over the frontal region) and the upper surface or sides of the cerebellum showed exudate in all our meningeal cases. The cisternae and pial tissues at the base, as a rule, were filled with pus; but Cases 3, 7 and 11 (an otitic case) failed to show involvement of the base.

The cases which failed to show involvement of the base failed also to show pus in the ventricles. Case 8 also showed no involvement of the ventricles. The ventricles, as a rule, were all equally involved. The exudate varied from opaque to turbid or flocculent. Although the exudate was elsewhere fluid, single drops of fibrinous pus drained into the posterior cornua of the lateral ventricles. The floors and recesses of the ventricles more frequently showed pus than the roofs and free non-vascular parts. The most destructive suppuration in the ventricles was found in Case 9.

The lesions of the brain substance were various. Eight cases showed no focal lesion of the substance in the gross. Cases 1, 2, 9 and 11 showed acute red softening. Case 9 showed a small abscess. The areas of central encephalitis showed distinct and numerous puncta cruenta and punctiform hemorrhages in the midst of tissue pinker than normal, plastic or friable and edematous.

The spinal cord was affected in those cases in which the tissues at the base showed pus. The pus in the cord membranes occurred frequently in the same discontinuous sheets characteristic of the cortical exudate.

The dura mater was occasionally distended. The venous sinuses, as a rule, contained crural clots. Case 12 showed sinus thrombosis on the side opposite to the mastoid operation. Cases 11 and 12 were infectious, both of otitic origin. In the other ten cases the middle ears were normal. Case 9 showed exudate in the cribiform plate, but the nasal cavities were free. In the cases with exudate at the base, the sheaths of the fifth nerve, the Gasserian ganglia, and the tissues about the pituitary body sometimes showed frank pus.

The other organs offered some things of note. Thus, all cases, except the otitic cases (9 and 12) (in Case 12 the examination was limited to the head), showed acute lesions in the lungs, lobar pneumonia in Cases 2, 5 (organizing), 7 and 8; bronchopneumonia in Cases 1 and

10; edema and congestion in Cases 3, 6 and 9; encysted pleurisy in Case 4. These lung lesions were probably responsible for the origin of some brain infections. The same doubtful correlation occurred in our series of brain infections with *Staphylococcus pyogenes aureus*, in which focal pulmonary lesions were either grossly prominent or made out microscopically in all six cases.

Aside from the lungs, the organs of the trunk showed little. Case 5 was a case of malignant endocarditis (aortic). Case 4 showed, in addition to encysted pleurisy, an acute pericarditis.

Chronic lesions, which might possibly have a bearing on infection, were found in a few cases. Half the cases (1, 3 (marked), 6, 7, 8 and 10) showed arteriosclerosis; and, of these, Case 6 showed a hypertrophied, dilated and fatty heart. Case 4 showed chronic nephritis. Case 8 chronic adhesive pericarditis, Case 10 cirrhosis of the liver.

GENERAL SUMMARY OF MICROSCOPIC FINDINGS.

Alterations were found in several of the tissues, particularly in the meningeal connective tissue, the walls of the arteries and to some extent of the veins, and in the nerve tissue, under which may be considered the reaction of the subpial neuroglia and the immigration of polynuclear leucocytes.

The meningeal tissues contained numerous cells, chiefly polynuclear leucocytes and mononuclear elements in varying proportions. In Cases 3, 6, 8, 10 and in parts of Case 11 the polynuclear leucocytes plainly outnumbered the mononuclear cells. In Cases 1, 4, 7, 12 and in parts of Cases 5 and 11 there are more mononuclear cells. Cases 2 and 9 showed these cells in about equal numbers.

Phagocytosis of mononuclear cells for polynuclear leucocytes was best marked in Cases 1, 4, 5, 9, 11 and 12, in most of which cases the mononuclear cells outnumbered the polynuclear cells. Phagocytosis for bacteria was best marked in Cases 1 and 2 (the two cases of almost pure encephalitis).

The general distribution of the meningeal exudate was fairly constant. Certain central spaces in the pia mater were likely to contain masses of polynuclear leucocytes even in cases in which the perivascular tissues and the tissues at large were filled with mononuclear cells. Another characteristic was the distribution of the fibrin, which was found in abundance about the veins and in that part of the pia mater just overlying the nerve tissue. There was no evidence of focal necroses in the exudate, although portions of the exudate stained poorly in Cases 7 and 11.

The arteries of the meninges showed lesions in all the meningitic cases, but these lesions were not characteristic in Cases 1 and 2. The intima was lifted or dissected away from the elastica by an accumulation of cells, largely polynuclear leucocytes. All degrees of this process occurred up to occlusion of the lumen. The lesion was frequent and marked in Cases 3, 7, 8, 10, 11 and 12, less frequent in Case 4 (in which the arteries of the spinal pia mater were affected), and in Cases 5, 6 and 9.

Somewhat less common but more striking were the lesions in the veins (Cases 5, 6, 7, 8, 12 and in some other cases to a minor degree). The walls of the larger veins, especially the large sulcal veins, showed the process more distinctly than the venules. In the walls of the venules there was occasionally a thorough infiltration with polynuclear leucocytes and minor proliferative changes; but in the larger veins there was a promi-

nent overgrowth of lining cells, among which the polynuclear leucocytes lay in a variety of ameboid shapes.

Case 6 was distinguished by the presence in the walls of numerous minute mural organizing thrombi (ten, for example, crosscut in a section of a vein about 1 mm. in diameter). Case 12 (a case of sinus thrombosis) showed occlusion of small veins of the pia mater also.

The reaction of the nerve tissue to the infection may be considered under the head of vessels, neuroglia and nerve cells with their adnexa.

The vessels of the cortex showed adventitial infiltration with polynuclear leucocytes in various degrees. Case 1 showed great accumulations of phagocytic cells about some vessels. The nerve cells failed to show notable or any rate constant changes.

The neuroglia exhibited, in many cases, a tendency to cell increase in the subpial layer. Three cases (6, 9 and 11) showed numerous mitoses. Case 6 showed mitoses among cells regarded as satellite cells. Cases 1, 3, 4 and 5 also showed cell changes in the neuroglia, eccentrically swollen cell bodies, multiple nuclei, or fibrils in apposition to cell processes. In Cases 2, 7, 8, 10 and 12 neuroglia changes were few or absent. In Case 2 (fulminant case in a boy of 10) the original layer of neuroglia was thin and the involvement of the meninges slight. In the other cases which showed no acute neuroglia change the original subpial layer happened, as a rule, to be dense. This character of the original neuroglia, however, can scarcely govern the occurrence of acute changes, since Cases 3 and 6 had dense subpial neuroglia, but marked acute changes.

The cortex was penetrated by polynuclear leucocytes in most cases. This penetration was free in Cases 2, 4, 5, 9 and 12. Occasional or fairly frequent examples of leucocytes in the substance were found in all the other cases, except 7, wherein very few examples occurred.

EXPERIMENTAL MATERIAL.

Inoculations were made in guinea-pigs with different strains of the pneumococcus kindly supplied us by Drs. C. W. Duval and P. A. Lewis in the course of their pneumococcus work in 1905.³ The results of inoculation with the various strains (sixteen), as tested by the appearances in guinea-pigs killed four days after inoculation, were various, ranging from negative to pronounced suppuration. Work was pursued with a single organism only (C D 6 of the series isolated by Duval and Lewis). The same method, in general, was employed as in our work with *Staphylococcus pyogenes aureus*, the method of simultaneous inoculation of several animals and histologic examination of animals killed on successive days during the course of the disease.

As in the work with *Staphylococcus pyogenes aureus*, various methods of inoculation were employed. The intrapulmonary method, applicable in staphylococcus work, is not well suited to pneumococcus work in the guinea-pig. Subdural inoculations are effective, but are open to the usual objections that the destruction and hemorrhage produced by the operation obscure the results of infection.

Resort was had, therefore, to a method of inoculation by way of the orbit. The syringe needle is introduced at the line of reflection of the conjunctiva on the temporal side of the globus oculi. The bouillon culture is then slowly introduced into the tissues of the orbit. Exophthalmos follows, but subsides in a few minutes.

3. Studies on the Pneumococcus, C. W. Duval and P. A. Lewis, Jour. of Exp. Med., August, 1905.

There is occasionally transient circular progression toward the side of inoculation. This method may be modified by plunging the needle through the wall of the orbit into the brain. Since the conjunctiva, as a rule, is free from bacteria, the method of orbital inoculation effects entrance into the interior of the cranium more advantageously than other methods. This method is said to have been first used in rabies work. Other methods, as nasal and ear-plate inoculations, were used, but are not so good for general work as the orbital method.

We found difficulty in recovering the pneumococcus from the organs of the inoculated guinea-pigs and were unable to obtain a complete single series of daily stages of the brain lesion with positive cultures in all. It would be possible, doubtless, to obtain an unbroken series of positive cultures by using very numerous animals and the rabbit's blood agar culture medium employed by Duval and Lewis in their investigation. Positive results, however, were obtained in a sufficient number of brain cultures in the series with organism C D 6 (Series of Duval and Lewis).

The general result of the experimental work is as follows:

Of the four-day orbital inoculations, seven cultures gave slight or negative results; three cultures gave accumulation of chiefly mononuclear cells in the meninges; two cultures gave very slight exudation with congested veins filled or lined with polynuclear leucocytes; three cultures gave exudates (recalling many of the human exudates) with polynuclear leucocytes and mononuclear cells in various, about equal proportions; one culture gave polynucleosis.

A series of brains from guinea-pigs inoculated in the orbit with organism C D 6 showed the following:

Six hours after inoculation many veins showed leucocytes arranged as in the inert layer. The tissues about the base and cerebellum showed a light exudation of polynuclear leucocytes and considerable hemorrhage. In the exudate were occasional polynuclear leucocytes with deeply eosinophilic granulations. The third ventricle showed hemorrhage with occasional polynuclear leucocytes; the mural ependyma showed no changes. The brain substance was normal, except for a few shrunken and metachromatic nerve cells; there was no penetration of substance by polynuclear leucocytes.

The brains after one, two and three days would in many cases be difficult to pick out and arrange in series, on account of variations in the amount of exudate and hemorrhage. More and more cells of the mononuclear series entered; but it was hard to estimate these when far outnumbered by polynuclear leucocytes and to distinguish them from such cells normally present. In one brain, two days after inoculation, a few minute hemorrhagic abscesses were found.

The condition four days after inoculation is described more fully, since four-day material can be recommended for test work. Four days after inoculation the tissues between the laminae of the cerebellum and at the base are distended with a heavy exudate in which polynuclear leucocytes somewhat outnumber the mononuclear cells. Fresh hemorrhages in the pial meshes are few and small. An occasional phagocyte containing polynuclear leucocytes occurs in the adventitia of veins. Cells of the lymphocyte series occur, with now and then a plasma cell; but these cells occur in foci, whereas the polynuclear leucocytes and the mononuclear cells having vesicular nuclei are of general distribution. The

ventricles show slight hemorrhage, a light exudate of polynuclear leucocytes and occasional phagocytes containing polynuclear leucocytes. Penetration of the cortex by polynuclear leucocytes is frequent and is particularly free in the cerebellum, where leucocytes are found deep among the cells of the granular layer.

A comparison of the four-day material after subdural injection of equal amounts of the same culture shows that the subdural lesions are of more advanced character, in the sense that polynuclear leucocytes are fewer, pigment-containing cells more numerous, and karyokinetic figures in the adventitial tissues more frequent than in the orbital material.

The exudates, however, are in somewhat different loci, the exudate after orbital inoculation is largely basal after subdural inoculation over the convexity.

The pictures on succeeding days are only roughly open to serial arrangement from internal evidence. The ependymitis, not so marked as in our series with *Staphylococcus aureus*, plays a minor part. There is rarely any destructive encephalitis. We have, therefore, only the meningeal picture, which as a single guide is unsatisfactory.

In from two to five weeks there was no longer evidence of disease in our series, except a multiplication of glia cells along the meninges and beneath the ependyma. The latter we are as yet unwilling to ascribe to the effects of the pneumococcus, since in many guinea-pigs the process is found from other causes. Mitoses beneath the ependyma are occasionally seen at various points in the series.

GENERAL SUMMARY AND REMARKS.

The foregoing is a report of cases grouped together as showing effects of pneumococcus brain infection. The clinical and anatomic varieties which they exhibit are only in part explained on present evidence. A long series of cases with parallel differential work on the best bacteriologic lines will be required to settle questions brought up by the various extent and effect of lesions like arteritis and phlebitis, by the varying prominence of polynucleosis and mononucleosis in the meningeal exudate, by variation in the phagocytic properties of the cells involved, and by the varying extent and character of the attendant cellular gliosis.

Clinically viewed, these cases are quite ill assorted. The group includes fulminant and wholly obscure cases, cases not to be told from severe pneumonia, clearly otitic cases, septicemic phenomena, and cases a week old or longer which are clearly cerebral or meningitic in character.

Anatomically viewed, the pneumococcus produces in the meninges and brain substance of man a type of inflammation in which cellular exudation and fibrin formation are prominent.

The picture postmortem varies from focal or diffuse red softening to purulent leptomeningitis and ependymitis and occasionally abscess formation. The meningeal exudate is almost constant on the convexity. The base is frequently involved and, with the base, often also the ventricles and the cord.

The histologic picture is more various than the anatomic picture. The meninges contain a cellular exudate which varies in the proportion of polynuclear leucocytes and mononuclear cells. Phagocytosis on the part of mononuclear cells for polynuclear leucocytes is best marked in cases in which the mononuclear cells outnumber the polynuclear leucocytes. The meninges in individual cases are fairly constant in the cell proportions

found. Fibrin is found about the veins and adjacent to the nerve tissue.

The arteries characteristically show lifting of the endothelium by cellular exudate. The veins often show proliferative changes in the intima with infiltration by polynuclear leucocytes (characteristic in large sulcal veins). Two cases showed mural thrombus formation in the veins.

Seven cases out of twelve showed increase or other signs of change in the neuroglia, especially of the subpial layer.

Penetration of the cortical tissue by polynuclear leucocytes is almost constant.

Orbital inoculations in the guinea-pig showed remarkable variety in the results with different cultures. With the cultures yielding positive results, a general but not constant tendency is to the production of exudates with a high proportion of mononuclear cells of the phagocytic series. A series of orbital inoculations with culture identical throughout exhibited clearly the same tendency. The exudation of polynuclear leucocytes is primary, however, and may be noted in six hours. The exudate is at its height in three, four or five days and leaves no trace in from two to five weeks. Ependymitis and encephalitis are not prominent. The guinea-pig inoculations, as a rule, produce no clinical sign.

THE DUMB-BELL INTESTINAL ANASTOMOSIS.

A PRELIMINARY REPORT ON A NEW MECHANICAL DEVICE
AND A NEW METHOD FOR EITHER INTESTINAL
APPROXIMATION OR ANASTOMOSIS WITH
THE STOMACH.*

JOSEPH B. BACON, M.D.

Surgeon to the St. Francis Hospital.
MACOMB, ILL.

The numerous methods of suturing that are described and the various mechanical devices that are demonstrated, even in our recent standard text-books of surgery, prove that the ideal method for intestinal approximation of anastomosis has not been discovered. Some of the methods of suturing have been successfully used by surgeons in a series of cases until they were almost ready to declare the method all that could be desired, when a sad accident occurred and the postmortem showed a defect in its workings. The same may be truthfully said of all the mechanical devices up to the present time.

The new method of operating and the new device here explained is the result of a year's work. I began with the idea that, in an end to end approximation of an intestine or an anastomosis of the intestine with the stomach, either where the severed end is used to make the anastomosis or with a lateral union, all of the connective tissues must be incorporated in the fixation method in order to safeguard against leakage, and also to get a firm safe union. This is what nature does in all cases in which one organ becomes agglutinated to another, and ultimately becomes anastomosed as a result of septic infection. After experimenting with one device after another, I finally succeeded in making this simple hollow dumb-bell accomplish the desired result. It simply acts as a hollow cylinder for the passage of liquids and gas, and at the same time gives a base on which we can tie all the connective tissue in one firm grasp by means of a rubber or silk suture of coarse fiber, and thus have a firm union for three or four days while the serosa and muscularis are becoming united by an organized lymph

in their new position. In from three to four days the organized tissue is a safe barrier against leakage. The ligature necroses through the connective tissue by this time and frees the device.

The dumb-bell is made of aluminum and is very light. There are three different sizes, one for children, one for adults and one for the colon. This same method may be used with a dumb-bell moulded from soft rubber or from any digestible material, but I prefer one of aluminum, as it can be made small, is light, has a definite strength so that one can do a definite work and know what to expect during a definite time.

We desire the connective tissue to hold at least for three days and prefer it to hold for five. My experiments on pigs proved that the dumb-bell is freed after from four to six days. The rubber ligature should be firmly wrapped around the tissues and the dumb-bell twice, then securely tied with several knots. The knots and ligatures are left within the canal and the quantity of ligature can make no difference. The ligature material should be coarse, so that it will necrose through slowly, hence use a rubber band about one-fourth inch broad (or heavy braided silk). Silk or linen sutures are not so safe as rubber in the hands of a beginner, as any sawing motion in applying the ligature might cut through and thus necessitate reamputation of the gut and a serious prolongation of the operation.

Fig. 1.—Showing the two styles of the dumb-bells.

Operation for end to end approximation: The two ends of the bowel are secured by a suture at the mesenteric border, care being taken to include in this suture the V-shaped mesenteric triangles. Directly opposite the mesentery, on the periphery of the intestine, another suture is placed. Each of these sutures is tied loosely, as they are only used for the purpose of invaginating the two ends of the bowel. Two inches from the end of the intestine, along its peripheral border, an incision is made through the intestinal wall, one inch in length. This incision is made in the proximal end of the intestine, if it be enlarged, otherwise on the distal end. A pair of forceps is now passed through the incision and into the end of the intestine and the tension sutures secured and drawn through the incision. Now steady the mesenteric border of the intestine between thumb and finger, and drawing the sutures, invaginates the two ends of the intestine into each other and through the incision. The dumb-bell is now placed into the ends of the invaginated intestine and the ligature applied at a distance of one-half inch from the ends of the severed intestine, encircling it and the handle of the dumb-bell. Disinvaginate by gentle traction and pressure on the dumb-bell; reunite the peripheral incision by a Czerny-Lembert or Gely suture. Then complete the operation by suturing the mesenteric opening.

The three sizes of the dumb-bell can by the ligature method be made to fulfill any requirement in any operation from the cardiac end of the stomach to the rectum.

* Read before the Chicago Academy of Medicine, 1905.

In doing a gastroduodenostomy an opening is made on the ventral wall of the stomach one and one-half inches in length. Through this aperture by means of a pair of forceps the dumb-bell is forced through the pyloric opening and dropped into the duodenum, where it can be pushed along by the hand within the abdomen to any selected point of the intestine, as the small omental cavity is opened for inspection, just as in any dorsal gastrotomy.

If there be a stenosis of the pylorus, an incision must be made in the duodenum near the pylorus and the dumb-bell placed in the duodenum, and this incision sutured. When the point is selected, with the right hand seize the dumb-bell from within the stomach with tenaculum forceps, then invaginate the duodenal wall and

Fig. 2.—Traction sutures grasped by forceps A and B.

dorsal stomach wall through the former incision on the ventral stomach wall by pressing the ventral wall down over the dumb-bell. Tie a firm ligature of heavy silk, reinforced by a rubber ligature, to insure uniform pressure, and necrosis.

Precaution must be used in not selecting a dumb-bell of more than one-half inch in

Fig. 3.—The traction sutures in place.

diameter, or excessive amount of the peripheral side of the small intestine will be ligated.

For uniting the severed end of the ileum to the site of the colon push the dumb-bell into the end of the intestine out of the way, throw a pursestring ligature around the end of the severed intestine, and leave the needle threaded. Select the point of the colon for anastomosis; nearly opposite this point open the colon by an inch incision, preferably in the tenia coli. Now insert the needle at the previous point selected and pull it out through this incision, and draw the side of the sigmoid and the end of the intestine into this incision. Now force the dumb-bell forward to the end of the intestine and place the ligature over the small end of the dumb-bell. Suture the opening into the colon and also the mesentery of the small intestine.

Where the cecum has been amputated the work can be done through the end of the colon before it has been sutured. Experience has taught us that the small intestine should never be united end to end with the large intestine, but always lateral above a newly-made cecum.

A specimen removed twenty-four hours after the op-

eration showed absolutely no leakage, the ligature and dumb-bell were firmly in place and a safe protective band of lymph was becoming organized. Especially at the dangerous mesenteric border can the accurate union be noticed. The strangulated ends of the intestine external to the ligature were very much hypertrophied, and dilated the intestine over the small end of the dumb-bell. For this reason I have made the opposite end of the dumb-bell one-fourth inch larger, so as more accurately to coapt the surfaces during the first twenty-four hours.

A second specimen, taken forty-eight hours from the time of the operation, showed very firm organized lymph. The strangulated rim that was hypertrophied in the other specimen was receding here. The ligature, where the intestine was dissected, still held firmly and could not leak.

In a third specimen, taken from a pig six months after the operation, there was great difficulty in finding the place of union. The lumen was normal and there was but a bare trace of circular cicatrix. It could only be

Fig. 4.—G and H. The ends of the invaginated intestine. F. Rubber ligature.

detected in a good light, and could barely be distinguished by touch. This pig weighed thirty-five pounds in May and 212 pounds when killed in November. The dumb-bell was evacuated on the tenth day.

A fourth specimen was secured from a pig

Fig. 5.—E. Position of the dumb bell after the ends of the intestine have been disinvaginated.

8 months after the operation. There was but a very slight limitation of the intestine. The cicatrix was barely to be distinguished. On inverting the specimen it showed a beautiful line of union of the mucous membrane. The union could barely be felt, and only showed a circular ring with a minimum amount of cicatricial tissue. This pig weighed fifty-four pounds in April at the time of the operation, and 340 pounds when killed in December. The dumb-bell was evacuated in this animal in eight days.

The advantages of this method of operating are:

1. Simplicity of the construction of the dumb-bell; therefore, always ready.
2. Simplicity of the operation.
3. The absolute safeguard against leakage, as the ligature secures all of the connective tissue.

4. The short time in which the operation can be performed.

5. The dumb-bell cannot remain at the site of operation more than four or six days, as the connective tissue will all have been uniformly necrosed by that time.

6. The extremely light weight of the dumb-bell, its size and shape insure against the possibility of its lodging at any part of the alimentary tract.

7. No reinforced sutures are necessary.

8. The minimum amount of cicatricial tissue that ultimately remains.

ROENTGEN DIAGNOSIS OF DISEASES OF THE LUNGS.*

G. E. PFAHLER, M.D.

Director of the Roentgen Ray Laboratory, and Assistant Physician to the Medico-Chirurgical Hospital; Lecturer on Medical Terminology and Symptomatology, and Demonstrator of Physical Diagnosis in the Medico-Chirurgical College.

PHILADELPHIA.

The importance of Roentgen examinations of the lungs is well expressed by the statement of Dr. Judson A. Daland, who says: "No chest examination is complete without an x-ray examination." In order to make Roentgen examinations of the greatest possible value, the best technic and the most careful and accurate interpretation must be employed.

As specialists in this special branch of medicine, we have made great strides in the perfection of our technic, but even with the most perfect technic in the making of a negative, much general knowledge of medicine, and much experience is still needed to interpret accurately the shadows obtained. Much assistance can be obtained from the study of the literature, but much more can be learned by the actual study of the negatives of the various pathologic conditions, associated with the clinical or the postmortem findings.

Postmortem examinations are seldom made immediately after the Roentgen examination, and in many of our cases they are never made. No one of us, therefore, has seen explanations of all the shadows obtained in our negatives. Neither has any one of us had the opportunity of studying all the pathologic conditions that we may be called on to examine. I have decided, therefore, to present before this body a number of Roentgenograms, showing a variety of pathologic conditions of the lungs, and to give my interpretation. In many instances, I know that my interpretation is correct, but in others, some of my colleagues may differ with me. It is with the hope of bringing out criticisms and thus of combining our experience in the study of diseases of the lungs, that I present this subject.

Fluoroscopic examinations of the lungs have been made almost since the discovery of the Roentgen rays, but the actual progress in the Roentgen diagnosis of diseases of the lungs dates from the beginning of short exposures. In this field excellent work has been done by Hulst, Kieder and others.

In order to study the lungs accurately, the negative must be made while the patient holds the breath. This will usually be from three to fifteen seconds. I have succeeded in making several good negatives of the chest of a child of 9 years of age in one-tenth of a second. Such short exposures are not necessary in the study of the lungs, and are necessary for the accurate study of the heart.

As a rule, a careful physical examination should precede the Roentgen examination, not because it will modify the shadows, but because it will enable the Roentgenologist to interpret those present, and may modify the method used, and thus make a second examination unnecessary. The greatest field of usefulness of the Roentgen rays in lung diseases is the study of tuberculosis. Here the lesions can be recognized earlier and more accurately than by any other method. Besides assisting in making a diagnosis, it is the most valuable and the most accurate method of recording the lesions at the various stages of the disease, and thus enables the physician to estimate the value of his therapeutic procedures.

METHOD OF MAKING THE EXAMINATIONS.

I have practically discontinued the use of the fluoroscope, because of its inaccuracy and because of the dangers attending its use. By the use of the modern devices for the protection of the operator at least one of these objections can be removed; still, I feel that a fluoroscopic examination is not necessary. Generally, a negative should be made with the plate posterior to the patient and another with the plate anterior to the patient, so as to give proper value to any lesions lying near to the surface, and in order, to recognize any thickening of the pleura. As a rule, the patient should be placed in the recumbent posture, except when pleural effusion is suspected, in which case the patient should be examined in the sitting posture. The tube should be placed at a distance of from 18 to 20 inches from the plate. The time of the exposure will vary with the time that the patient can hold the breath, and this time should be accurately determined by testing the patient several times before attempting to make the exposure.

INTERPRETATION.

The proper interpretation of the negative is more important than the making of it and fully as difficult. The negative itself should be used for study.

Old calcified tubercles give the most decided shadows, and lesions of this kind can be recognized as small as one-eighth of an inch in diameter. Old scars or fibrous tissue cast a less dense shadow and require larger lesions, but they can usually be recognized by their band-like appearances.

Consolidations vary in the density of their shadows with the size of the lesion; but an area one-half inch in diameter can be recognized in an emaciated person. In one patient, who was very much emaciated as the result of tuberculosis of the peritoneum, I succeeded in showing little tubercles the size of a pin head. Consolidations seldom occur singly, therefore, they give the lung a mottled appearance, except when there is massive consolidation. Finally, the consolidation can be recognized by comparison of the suspected area with that of the opposite lung or with the other parts of the same lung. The tubercular deposits, or the affected areas lying in different planes, are thrown on the plate in one plane; therefore, on superficial observation, one might conclude that a greater proportion of the lung is affected than is correct. That is, the whole lung might show a mottled appearance, and the false conclusion be drawn that no healthy lung tissue remained. This mistake need not be made by an experienced observer, because if the whole lung or lobe is involved the degree of general density will be much greater than when only scattered areas are involved, and the density will approach that of the shadow of the heart. Even when a whole lobe is involved, the shadow is rarely uniformly dense, because the

* Read at the Annual Meeting of the American Roentgen Ray Society, Baltimore, Sept. 28-30, 1905.

lung is rarely uniformly consolidated. There are likely to be small or large areas of cavity or compensatory emphysema associated with the consolidation.

Cavities are usually recognized by their increase in transparency surrounded by the shadow of consolidation. If the cavity is large there will be little difficulty in recognizing it. If, however, the cavity is small or is resting on a large area of consolidation, or thickened pleura, it is less easily recognized. Under favorable circumstances, a cavity one-half inch in diameter can be made out.

Emphysematous areas are also noticeably transparent. A dense shadow may be found on one side of this area, but it is likely to have the other side continuous with more or less healthy lung tissue, and therefore can be differentiated from cavity.

Pulmonary Abscess.—This diagnosis can not be made entirely by means of the Roentgen ray, but when it is suspected, it can be more accurately located by the assistance of the rays. The radiographic appearances will not differ materially from those of cavity appearances, except that the surrounding area of consolidation is likely to be larger in proportion to the size of the cavity. Since the two may be associated, however, the difficulties are increased, and the findings must be carefully compared with the physical signs before operating.

Pulmonary Gangrene.—The remarks made in connection with pulmonary abscess will apply to pulmonary gangrene, except that instead of the area of consolidation being large and the cavity small, in this instance, the cavity is more likely to be large and the surrounding wall small. The conditions and the shadows will vary with the stage at which the examination is made. The odor will usually suggest the diagnosis, and the rays will be useful in locating the area for operation.

Pneumonia.—The fluoroscope shows a dense shadow in the affected area in pneumonia, and the movements of the diaphragm are diminished on the affected side, partly because of the increased density of the lung and partly, at times, because of an adhesive pleurisy. Williams was one of the first to apply the rays in the study of pneumonia. He depended almost entirely on the fluorescent screen. De la Camp¹ has recently made some interesting studies in pneumonia, in which he used the plate. He finds that the rays will localize the lesion more accurately than can possibly be done by any other means. This is especially true when the lesion is centrally located, or at a distance from the surface. It is in this class of cases that the rays will be found most useful, because it is in them that ordinary physical signs so commonly fail.

The Roentgen ray is also a most useful adjunct in the diagnosis of lesions not centrally located, especially when such lesions are situated beneath the scapula, or when small consolidations are surrounded by areas of compensatory emphysema. Compensatory emphysema assists in outlining the lesions by means of the Roentgen ray, because of its greater transparency, but offers considerable hindrance when the ordinary physical signs are depended on.

De la Camp found even in lobar pneumonia that the whole lobe is seldom uniformly consolidated. He often found by means of the rays an extension of the process into another lobe or into the opposite lung, when ordinary physical examination failed to reveal such lesions. The rays were found of great assistance in the study of the cases during the stage of resolution. In some

cases, months were required for the lung to recover completely. The rays show lesions long after the physical signs are negative. In one case in which the patient complained of pain in the region of the heart, which persisted four months after the crisis, and after all physical signs were negative, the Roentgen examination showed a fibrous band about one-fourth of an inch broad binding the left side of the diaphragmatic pleura to the pericardial sac. Other symptoms of obscure origin following pneumonia may often be cleared up by the aid of a Roentgen examination. The same principles that have been described in the interpretation of tubercular negatives will apply to those of pneumonia. The areas involved, however, are usually larger and therefore more easily recognized.

Emphysema.—In a typical case of emphysema one is struck by the great transparency, which is greater than in any other condition of the lungs. This transparency affects both lungs, as a rule. The ribs will be found to extend outward from the spinal column at more nearly a right angle than normal. To distinguish the lesser grades of emphysema or to recognize local areas much more experience is necessary, for, then, one must keep in mind the normal Roentgenogram of the same age and general development, thickness of the chest walls, etc., and made under similar conditions.

Collapse of the Lung.—Collapse of the lung probably will not be recognized by means of the Roentgen rays when the area involved is small, but when the area is large it gives an appearance very similar to that of consolidation. It is more uniform and more sharply outlined than in tuberculosis, and it involves a lesser area than when pneumonic consolidation is present.

Thickening of the pleura is a common affection, occurring both independently and in association with tuberculosis of the lungs. This condition is recognized in the Roentgenogram as a uniform shadow of only slight density. The density will vary with the degree of thickening. This shadow is then seen to shade gradually at its edge into the surrounding clear space. If the surrounding lung is healthy, there will be little difficulty in recognizing a moderate thickening.

If, however, the thickened pleura is overshadowed by consolidated lung it becomes much more difficult, and at times impossible. Here experience alone will serve as a guide. In order to study the pleura accurately, both an anterior and a posterior plate should be made.

Pleural Effusion.—Pleural effusion is best recognized by placing the patient in the sitting posture, with the plate or tube posteriorly and the tube anteriorly. To make a Roentgenogram, place the patient in a chair with a large board resting against the back on which the plate is supported. The pleural effusion gives uniform but not a very dense shadow, occupying the lower part of the pleural cavity. The upper level has a curved but not irregular line. In uncomplicated effusion the shadow is even more uniform than that of a thickened pleura. The pleural thickening will also be recognized by its irregular border, which is never a line. The shadow is less dense than would be produced by consolidation of the lobe of the lung.

Pneumothorax.—Pneumothorax is recognized by the area of great transparency, greater than emphysema. This area is elongated in a vertical direction, as a rule, and occupies the lower lateral portion of the chest. Toward the median line may usually be seen the thickened pleura and the diseased lung. The heart is commonly displaced to the opposite side.

¹ Fortschritte u. d. Gebiete d. Röntgenstrahlen, April 30, 1905.

Hydropneumothorax.—This condition is more common and forms one of the most interesting fluoroscopic pictures that can be found. In addition to the findings of pneumothorax, the fluid at the base of the pleural cavity may be seen to move with each respiration, or each movement of the body. If the patient is slaken, the fluid is seen to splash.

Hemothorax.—I have examined two cases of this character. Both showed a more dense shadow than would be produced by any other form of pleural effusion.

Consolidation and Pleural Effusion Combined.—In a case of this kind the shadow of the pleural effusion was seen to extend to the fifth rib on the right side and to the seventh rib on the left side. The consolidation of the right middle lobe showed through the effusion, and was distinctly more dense. Probably no condition will give more difficulty in recognition than consolidation surrounded by an extensive pleural effusion. In this particular case there were the peculiar physical signs, tubular breathing and bronchophony extending throughout the area of pleural effusion. By making Roentgen examinations in all such cases we may find that consolidation of the lung is present and that it is the cause of the peculiar physical sign. This sign is probably due to the transmission of the larger sound waves from the bronchi, through the consolidated lung to the fluid in the pleural cavity, and thence through the chest walls to the air. The striking of two stones together will convince most people that fluids will transmit sound, but these sounds must be of the louder and coarser variety, therefore vesicular breathing is not transmitted through an effusion.

Subphrenic Abscess.—The difficulty in recognizing many of these cases is appreciated by all who have had much experience, and therefore any aid will also be appreciated. In a case examined about two years ago by means of the screen, I was able to see a decided displacement of the diaphragm upward as far as the ninth rib, and absolute immobility was noted on the right side. The left side of the diaphragm was seen to move two and one-half inches. The Roentgen examination will also eliminate some of the conditions with which this may be confused, such as pneumothorax, encysted pleural effusion or empyema.

CONCLUSION.

In general, the diagnostic value of the evidence obtained through the Roentgen ray will depend very much on the skill and the experience that the operator has had, both in Roentgen work and in general medicine. Glowing reports of cases, beautiful Roentgenograms and the enthusiastic claims of manufacturers lead many physicians to conclude that all they require to get good results is an instrument. This is as absurd as to conclude that all a physician needs to enable him to do good surgery is a set of good surgical instruments. Much harm has been done both in diagnosis and in treatment by the possessors of this erroneous idea. Much skill, both in the preparation and the interpretation of a negative, is needed. This is obtained only through daily practice. The ability to read a negative will also depend in great part on the physician's knowledge of general medicine.

Physicians' Business Methods.—If the physician would conduct his business on a legitimate foundation, and adhere to it by pushing methods, he would be able to reject commissions from druggists, could pay his bills like a gentleman, care better for his family and himself, and gain the respect of the community. Then his word in municipal and legislative worlds would be followed and appreciated.—*Northwestern Lancet.*

FIRST AID TO THE INJURED;

ITS IMPORTANCE TO RAILROADS FROM A HUMANE AND ECONOMIC STANDPOINT.

MARCUS H. THOMAS, M.D.

Indiana State Surgeon, the National First Aid Association of America.

HUNTINGTON, IND.

THE RAILWAY ACCIDENT.

The instruction of railway employes in first aid to the injured is just in the advent of its practical employment. It is at this time a matter of comment with the secular press and the public that, in spite of modern inventions and appliances, the railway accident is apparently inevitable and, paradoxical as it may seem, is on the increase.

The block signal system, the patent coupler, the air-brake were all heralded as life-saving devices that would practically eliminate the danger to the employe and the passenger, and while unquestionably much has been accomplished by these inventions toward minimizing the casualty list of the modern railroad, yet other influences have counteracted their good results, and the fact remains that the railroads daily maim and kill a much larger per cent. of employes and traveling public than they should for their own moral and economic welfare.

In time of peace (a condition which, by grace of God, exists in our country with only trivial interruptions) the railway accident casualty list is rightly looked on as the chronology of the greatest menace to life and limb in our routine existence.

STRIKING STATISTICS.

Setting aside the millions of passengers carried on American railroads during the year and the proportion killed and injured, and eliminating for the sake of brevity the bystanders and trespassers killed and injured annually, I will consider the casualties among railroad employes alone.

Approximately 1,300,000 persons form the standing army operating the railroads of the United States. Statistics show that during the year 1904 the fatalities by accident among this number were one in each 500. One in every twenty-four was injured. Much has been said of the humane feature of first aid instruction among the armies of the civilized world, where it is now recognized as an indispensable and inseparable feature of the education of the soldier. From the humanitarian standpoint the same argument will hold with reference to the alleviation of the suffering among the victims of the inevitable railway disaster.

Space forbids an exhaustive review of this subject from the many points of advantage that can truthfully be ascribed to it, but I will say a word on what may be considered its more sordid advantage and the one which should be of paramount importance to the railroad, with whom the economic question is always one of vital interest.

For the past six or eight years I have given special study to negligence and railway accident law, and feel that I have become competent in its application to personal injury cases.

The steam railroads of the United States pay annually in damages to injured persons 00.74 per cent. of their gross earnings. This is seemingly a trifling decimal, but in coin and currency it amounts approximately to \$14,000,000. In addition to this sum \$7,000,000 is spent annually in the maintenance of a legal department, one-half of which expense may safely be attributed to the defense and settlement of personal injury damage suits.

These figures do not cover the total expense of injuries by common carriers by any means. This compilation pertains solely to the steam railroads, while the interurban electric lines and local street railway lines increase the above totals many fold. Particularly do the local street railways add enormously to the list. It is estimated that the Metropolitan Elevated of New York alone pays annually \$2,000,000 for personal injuries and has constantly on hand nearly 6,000 suits of this nature. The Brooklyn Rapid Transit Co.'s annual personal injury budget is in the neighborhood of \$1,000,000.

The ease with which evidence can be purchased and the ubiquity of the professional damage suit lawyer in the large centers of population gives the simulator and imposter a larger percentage of successful chances than with the transcontinental railroad. In accident to passenger or employé, no matter how trivial in nature, the damage suit sequel should always be borne in mind by the attendant.

NEEDS OF THE SITUATION.

The study which I have given railroad accident and injury from the forensic viewpoint has impressed on me certain deficiencies in railroad practice which, in my opinion, can be readily eliminated and which would result in great saving to the operating companies.

I am a firm believer that herein is a new field for the student of medical jurisprudence and surgical practice. I contend that the surgeon who is qualified in negligence law is in position to render the most effective and economic service as adjuster of personal injury claims.

There exists to-day in most of otherwise well organized railroads a lack of co-ordination between the legal and surgical staffs as a result of the one failing to grasp the importance of the technic of the other. This proposition operates with equal force conversely.

It is into this breach that the medicolegal claim adjuster can step to the assistance of both departments and with economy to the company. Dr. Pearce Bailey of New York,¹ an authority on forensic medicine, in a personal letter, says: "I believe that the very best adjuster that a railroad can have is a medical man with knowledge of negligence law."

I call the attention of railroad surgeons particularly to a close study of this subject. Under existing conditions the settlement of personal injury claims rests wholly with the legal department, and notwithstanding their best efforts the annual damage account shows increase with most railroads. Considering the enormous amount of money involved, it would seem to me to justify economical experimentation along other lines in search of a more effective method of control.

SKILFUL FIRST AID.

The National First Aid Association of America, under the presidency of the noble and renowned Clara Barton, is propagating the cause of first aid among railroads and other civil organizations and hopes soon to bear to the carriers of human freight the same quasi-official and inseparable relation that the Red Cross does to the military of the civilized powers.

Every railroad surgeon realizes the truth of the statement that in time of accident the uninitiated are as likely as not to do the wrong thing for the patient if any effort is made at all at temporary relief. A chew of tobacco from a syphilitic mouth applied to a mashed finger, or a filthy turpaulin bound round a compound fracture are worse treatment than absolute neglect.

By minimizing the danger at the time the accident is received, and by proper, helpful first aid intelligently administered, the opportunity for infection with the microbe of the damage suit is reduced and saving to the company accrues.

INSTRUCTION OF EMPLOYEES.

Combined with this service and in order to obtain the best results I advocate the instruction of employés in a few of the most essential points of negligence, which can readily be injected into the first aid instructions.

Dr. Pearce Bailey says in his book¹ that the very nature of a railroad accident (collision or derailment) renders all participants principals rather than witnesses to the injury of another.

Railroad attorneys and surgeons appreciate the difficulty often experienced in obtaining satisfactory evidence from employés in such catastrophes. The system which I advocate would include the instruction of employés in accident law points in a manner that would render them more competent witnesses.

In recapitulation I present to the serious consideration of railroad companies as a means of reducing very materially their damage claims:

(a) The instruction of trainmen and shopmen in first aid to the injured.

(b) The incorporation in this instruction of practical points on accident law.

(c) The employment in the claim department of a medical man, skilled in theory and practice of surgery and adept in negligence law, whose duty it will be to assist and advise counsel of the road, to bring about co-operation between the legal and surgical staffs of the closest possible nature, and last but not least, to be possessed of a fund of sound sense and a personality that will enable him to deal direct with the claimant.

I am confident that the adoption of the above plan will result in a net saving to a railroad company of from 10 to 20 per cent. of the amount now spent annually in payment for personal injuries, real and assumed.

THE TREATMENT OF THE RESULTS OF INFANTILE PARALYSIS.*

PRESCOTT LE BRETON, M.D.

BUFFALO, N. Y.

In none of the usual text-books can one find an orderly summary of the treatment of anterior poliomyelitis, after the subsidence of the acute stage. Even the orthopedic treatises do not group the varied conditions and present the manifold methods of treatment so that the general practitioner can readily decide what is indicated. This paper is an attempt to present the subject in a simple, concise manner, under varied headings, enabling one to refer quickly to the latest methods. Many operative procedures which have not proved satisfactory have been omitted. The literature is so extensive that only a few references are cited, although I have drawn freely from all sources.

The child which has suffered from an attack of infantile palsy is brought for advice because of:

1. Difficulty in locomotion.
2. Deformity.
3. Need of apparatus or of operation to improve existing conditions.

The causes of the deformity are:

1. The effects of gravity, e. g., toe-drop.

1. Author of "Accident and Injury; Their Relation to Diseases of the Nervous System." (D. Appleton & Co.)

* Read at a meeting of the Roswell Park Medical Club, Nov. 6, 1905.

2. The unopposed action of the sound muscles and their contracture, e. g., flexion of the knee due to paresis of the quadriceps, with contracture of the hamstring muscles.
3. Functional use of the part, e. g., flat foot following palsy of the tibial muscles.
4. Laxity of the ligaments, e. g., knock-knee or subluxation of the femur.

The treatment may be divided as follows: The principles of treatment; special conditions and their treatment; shoes and braces; operations.

THE PRINCIPLES OF TREATMENT.

The early indications, when the results of the diseases are beginning to appear, are:

1. To increase nutrition of the muscles.
2. To prevent deformity.

The following general means are employed:

1. Massage and warm clothing.
2. Electricity, both galvanism and faradism.
3. Functional use, as far as possible, to combat not only the atrophy of muscle but also of bones and ligaments.
4. Passive motion of each joint to its full range daily to prevent contractures.
5. A light night brace if the extremity lies in an abnormal position during sleep.
6. A shoe or apparatus during the day to allow proper support during use. Also, according to Bradford and Lovett, to develop normal reflexes and muscular co-ordination. It is a general rule that when in the act of walking the extremity is thrown into any abnormal position, apparatus or other treatment is indicated.

The later indications, when treatment has been neglected, are:

1. To correct existing deformity, when present, often improving the mechanical conditions by a special operative procedure.
2. To support and keep the parts in their proper relation after such correction.

By the following means:

1. Correction.
 1. By massage and passive motion.
 2. By force while the patient is under an anesthetic.
 3. By a series of plaster casts at rapid intervals.
 4. By tenotomy.
 5. By one or more operations—i. e.:
Nerve transplantation.
Tendon transplantation.
Arthrodesis.
Osteotomy.

These operative procedures are described collectively after the discussion of special conditions. They have been found of great value in recent years and are being employed to a large extent to the exclusion of mechanical aid.

2. Apparatus designed for the individual case.

SPECIAL CONDITIONS AND THEIR TREATMENT.

1. *Talipes equinus*, or toe-drop, is one of the commonest forms, in which the fore-foot falls down at the medio-tarsal and ankle joints, due to paresis of the entire anterior tibial group. If the deformity is not fixed by contracture, the treatment is as follows, beginning with the simplest plan and proceeding to severer methods:

1. An elastic garter attached above the calf or to one of the waistbands, ending in a tape, which is sewed to the vamp of the shoe.
2. A shoe extended far enough up the calf to keep the foot at a right angle.
3. A brace, consisting of one upright, a band above the calf and a joint opposite the ankle, allowing plantar flexion only to a right angle. The lower end attached

to the heel of the shoe or to a footplate, which goes inside the shoe.

4. Nerve transplantation of the anterior tibial nerve and the branches to the tibialis anticus into the musculocutaneous nerve.
5. Tendon transplantation of a portion of the tendo-Achilles around the inner side of the ankle, attaching the reflected tendon just above the ankle joint to the tibialis anticus or extensor communis digitorum.
6. Arthrodesis of the ankle joint, i. e., an artificial stiffening of the joint to hold the foot at a right angle.

If the tendo-Achilles is short, preventing dorsal flexion, several courses may be followed:

1. When the leg is short and there is no discomfort from the contracture, it may be possible to build up the heel inside the shoe to conform to the bottom of the foot.
2. Usually forcible correction under an anesthetic is advisable, by manual force or with the Thomas wrench. If *cavus* is present, tenotomy of the plantar fascia followed by forcible reduction of the high arch is advisable. A plaster dressing for a few weeks and then the use of the brace mentioned above.
3. The tendo-Achilles may be lengthened by open incision and a portion of the tendon transplanted to the front of the ankle. Arthrodesis of the ankle joint may be performed in addition.

When the contracture is of slight degree, allowing dorsal flexion to a right angle, the patient may develop "genu recurvatum" or back-knee, in which the knee is overextended in order to bring the sole flat on the ground. This condition, when well-marked, requires a brace extending to the upper thigh or pelvis with a joint at the knee allowing extension to a straight line only. When the contracture is severe, the opposite condition will prevail, and the patient will walk on the fore-foot with flexion at the hip and knee. Operation on the foot is necessary, followed temporarily by the wearing of a brace.

2. *Talipes equino-valgus*, or toe-drop with flat-foot, is fairly common, due to palsy of the tibialis anticus, or tibialis anticus and tibialis posticus. The great toe is often drawn backward in the position of the hammer-toe because of the overaction of the extensor longus pollicis. The treatment:

1. A shoe to hold the foot at a right angle and support the arch.
2. A brace, as before, with flat footplate and stop-joint at right angle to prevent plantar flexion.
3. Nerve transplantation, as for *talipes equinus*.
4. (a) Tendon transplantation of the peroneus brevis behind the ankle under the tendo-Achilles to be attached to the periosteum of the scaphoid. Also the peroneus tertius across in front of the ankle and beneath the anterior tendons to be attached to the same point. It is an excellent plan to supplement these steps by arthrodesis of the medio-tarsal joint, or at least arthrodesis of the astragalo-navicular joint.
- (b) Another excellent method is to transplant the extensor longus pollicis to the scaphoid, running the tendon through a canal bored in that bone, turning it back and suturing the free end to the periosteum and to itself, thus forming a check-rein, which prevents valgus and toe-drop. Arthrodesis of the astragalo-navicular joint will further strengthen the improved position.
5. For an old case which shows considerable rigidity it may be necessary to do a cuneiform osteotomy, which includes the astragalo-navicular joint.

3. *Talipes equino-varus* is the most common of all the deformities of the foot. It is due to paresis of the anterior muscles with weakness of the external or peronei muscles.

1. A shoe by which the foot is held up and the forefoot swung outward at medio-tarsal joint, sometimes with a slight raise in the inner sole under the cuboid bone.
2. A Taylor clubfoot brace, which has a sole plate and a single inner upright so constructed that when the brace is on, the varus is corrected.
3. If passive correction is impossible, overcorrection by force, with or without tenotomy, or one of the following operations may be advised:
4. Tendon transplantation:
 - (a) The outer half of the tendo-Achilles may be inserted into the distal ends of both peronei.
 - (b) The extensor longus hallucis or the outer half of the tibialis anticus may be passed across the foot under the other tendons to be fastened to the periosteum of the cuboid bone. Arthrodesis of the calcaneo-cuboid joint is a useful adjunct.
5. In a rigid case of long standing a cuneiform osteotomy including the calcaneo-cuboid joint is indicated.
4. *Talipes varus* is due to palsy of the peronei muscles, which weakness allows the fore-foot to be drawn inward. Toe-drop, of course, is absent.
 1. For a mild case, in which motion is free, a shoe which holds the foot correctly will suffice.
 2. A tendon transplantation just as for talipes equinovarus.
 3. Cuneiform osteotomy, including the calcaneo-cuboid joint.
5. *Talipes valgus* is a rare condition due to paralysis of the tibialis posticus in which a flat-foot is present.
 1. A shoe in which the insole is raised to support the arch and the front axis is swung inward to correct the valgus. Or a flat footplate of the usual type.
 2. Tendon transplantation and arthrodesis as for talipes equinovalgus.
 3. Cuneiform osteotomy.
6. *Talipes calcaneus* is caused by paralysis of the calf muscles, so that the foot is drawn upward by the anterior muscles. The os calcis becomes dorsi-flexed, causing cavus or "hollow foot," and the heel becomes less prominent. The cavus is the worst feature and is especially difficult to overcome.
 1. A shoe will often control a mild case.
 2. A brace as for toe-drop with the stop-joint arranged to prevent dorsal flexion.
 3. If the resistance to passive correction is strong, one may use a series of plaster casts in succession and then apply a brace. If the cavus and contracture are both fairly well marked, it is better to cut the plantar tissues, reduce the arch by strong force and apply plaster. Care must be used that the forefoot is not simply forced down, thus increasing the cavus.
 4. Whitman has used very successfully his operation of removal of the astragalus. He also shortens the tendo-Achilles, transplants the peronei into the os calcis and displaces the os calcis well backward, thus bringing the foot into a good position. Astragalectomy gives a strong and useful foot and the resultant shortening is not of great consequence. No brace is necessary afterward.
 5. Arthrodesis, before deformity is marked and resistant, is an excellent measure. The stiffening of the ankle joint tends to prevent deformity.
7. *Talipes calcaneo-valgus*, in which the fore-foot is drawn upward and to the outer side, is due to weakness of the calf muscles and the anterior muscles. It is fairly common.
 1. A brace, with footplate and strap around the foot to keep the foot down on the plate, may be employed, but experience proves that it is sometimes impossible to keep the forefoot in apposition to the plate.
 2. Tendon transplantation of the peroneus longus back of the ankle to be attached to the flexor longus digitorum, and the peroneus tertius across the front of the foot to be sowed to the tibialis anticus.
 3. Removal of the astragalus.
 4. Arthrodesis of the ankle joint, coupled with a transplantation of the peronei muscles.
8. *Talipes calcaneo-varus*, in which the fore-foot is drawn upward and to the inner side, is caused by the action of the anterior muscles overpowering weakened calf and exterior muscles. The treatment is similar to the last-mentioned condition.
 1. A brace.
 2. Removal of the astragalus.
 3. Arthrodesis of the ankle joint with transference of the extensor longus pollicis to the outer side of the foot.
9. *Dangle foot* is that weakened state where all the muscles have suffered and the foot assumes any position. Such a foot, however, is capable of giving good support when properly braced.
 1. A strong shoe, run high on the calf.
 2. A brace, allowing dorsal flexion only.
 3. Arthrodesis of the ankle joint is especially useful for this deformity.
10. *Contracted foot* is now a well-known deformity, which follows some years after an affection of the anterior muscles. The attack has been slight and often overlooked. The stronger muscles have gradually produced a high arch, or cavus, while the tendo-Achilles has shortened enough to prevent dorsal flexion beyond a right angle.¹
 1. A shoe with a high arch.
 2. Where there is much complaint of pain it will be necessary to divide the plantar tissues which have contracted, apply considerable force to reduce the arch, divide the tendo-Achilles and put the foot up in a corrected position in plaster. Later the patient wears a proper shoe.
11. *Paralysis of the anterior thigh muscles*, or quadriceps extensor, prevents the patient from extending the leg. The standing position is insecure, as he is apt to fall forward. In walking he has to swing the lower extremity forward, and often holds the hand on the front of the thigh to keep the knee from sudden flexion. If overextension is possible, back-knee is often developed, i. e., a locking of the joint by overextension while taking a step, the strain coming on the posterior tissues and crucial ligaments. If the hamstrings are shortened, the gait is very insecure.
 1. A Thomas knee brace, or ordinary brace, with external and internal bar, ending at the heel. Either no joint is allowed at the knee or else a lock joint, which has a mechanism to allow flexion in the sitting position. If there is a tendency to back-knee, a strap should be passed back of the knee to prevent hyperextension. Often some foot condition will require correction also.
 2. When there is resistant flexion of the knee, repeated plaster casts may effect improvement. Or a tenotomy of hamstrings and fascia and forcible correction. It must be remembered that a peroneal nerve may be overstretched and a temporary paralysis caused by the use of too great force or by a plaster cast which straightens too suddenly. It is a good plan to cut the cast as soon as applied in each case, as the peroneal nerve, on account of the binding of its branches, is particularly vulnerable.
 3. Tendon transplantation is now generally employed instead of tenotomy. The hamstring tendons are brought around the femur and sewed to the quadriceps tendon at the sides or just above the patella. The biceps is swung on the outer side and the semi-tendinosus and the semi-membranosus on the inner. Muscle grafting of the sartorius into the quadriceps is an adjuvant.

12. *Knock-knee* is a common result in infantile paralysis due to general weakness and laxity of ligaments. It may be corrected by a knock-knee brace or Thomas knee brace, or by an osteotomy of the femur above the condyles.

13. *Paralysis of the hip muscles* is regularly accompanied by palsy of other muscles below. If all the muscles are affected, dangle thigh results, but the sartorius and tensor vagina femoris are rarely involved. The position assumed is one of flexion and outward rotation of the thigh, with lordosis of the back and flexion or hyperextension of the knee. Weakness of the ilio-psoas causes loss of power of flexing the thigh. Adductor palsy makes the patient lift one thigh over the other by the hands if he wishes to cross his legs. Gluteal paralysis is the worst condition because the patient can not stand.

The treatment of palsy of the thigh muscles is by apparatus only. A brace with a pelvic band, with or without perineal bands, extending to the foot. For example, a Thomas knock-knee brace with pelvic band added. For both limbs, double braces are employed. For paralysis of the gluteal and back muscles a leather jacket with double braces is necessary, and if there is no power in the glutei, crutches also have to be used. This very disabling condition is rare, and sometimes in later years enough power returns or is developed to allow the case to walk without crutches. A free joint is allowed in the braces opposite the hip joint. Contracture of the tissues about the anterior spine, causing flexion of the thigh, necessitates a tenotomy of the same.

14. *The muscles of the trunk* are, as a rule, exempt, but may be severely attacked in cases showing a general involvement. Weakening of the abdominal muscles results in lordosis and a prominent abdomen, for which treatment is rarely required by support or jacket. General involvement of the back muscles induces kyphosis, chiefly in the dorsal region. Lateral curvature may be due to a short leg, or the attitude assumed from palsy elsewhere, or to the fact that the disease has attacked mainly one set of erector spinae muscles. In this last case, the convexity of the curve looks to the stronger side, because of the collapse of the chest wall and atrophy of the tissues. The stronger side develops and expands. The treatment of such curvature is by jacket, electricity and special exercises.

15. *In the upper extremity* Tubby has devised an operation for the relief of paralysis of the serratus magnus, causing winged scapula. An incision is made over the outer border of the pectoralis major, a part of its sternal portion is cut from its insertion into the humerus and subdivided. These subdivisions are transplanted into the four or five main serrations of the serratus magnus.

For deltoid paralysis, causing inability to abduct the arm, Hoffa transplants part of the trapezius into the deltoid, selecting appropriate adjoining parts.

For general involvement of the shoulder joint muscles, shoulder cap may be applied or an arthrodesis of the joint may be performed, and the forearm supported in a sling to prevent dragging on the shoulder and dislocation of the shoulder joint.

Weakness of the biceps may be combated by using a brace to hold the forearm at a right angle, or a portion of the triceps may be swung around the humerus and inserted into the biceps.

Weakness of the triceps has been modified by transplanting a part of the biceps into the triceps.

In the forearm, a flaccid condition usually exists. If

contraction is present it resembles the hemiplegic type, with pronation and flexion of the hand. In either condition the following tendon transplantations are valuable:

The pronator radii teres may be made to act as a supinator. Two incisions are made, one over each condyle of the humerus extending downward. The pronator is isolated, passed through a tunnel and fastened to the external condyle.

At the wrist the flexor carpi radialis is passed around the radius and sewed to the extensor carpi radialis longior, and the flexor carpi ulnaris is passed around the ulna and fastened to the extensor carpi ulnaris, thus providing for extension of the hand. The flexor sublimis digitorum tendons may be passed through the space between the two bones above the pronator quadratus, and fastened to the tendons of the extensor communis digitorum. This should improve the power of extending the fingers. These last operations are very valuable in other conditions than simply infantile paralysis.

Lock joint for the knee. AB, the uprights; C, free joint at knee; DE, spring lock; at D a projecting pin slips through the uprights at full extension, locking the joint; F, spring; I, base, attached to the upright, projecting solidly through to I, but pierced at J by transverse axis on which DE, moves.

SHOES AND BRACES.

There are a few practical points to be borne in mind when ordering shoes or braces. The object of a special shoe is to hold the foot in the best possible position and correct the deformity. If valgus is to be overcome, the front axis of the sole which reaches from the center of the foot to the toes, should be swung well inward, and a raise of leather built in the insole to raise the arch. If varus exists, the front axis should be swung outward, until the front and rear axes nearly form a straight line. A slight raise may be placed in the insole underneath the junction of the os calcis and cuboid to evert the foot slightly. The uppers often need strengthening opposite the ankle joint by whalebone or other means. It is often a good plan to place the foot on a square of paper, passively correct the deformity and then draw an outline of the sole, to serve as a guide as a ground plan of the sole if the shoemaker is not experienced. The shoes should be made to lace, and they can be made to fit more snugly if the lacing is carried down over the toes, instead of stopping back of the toes as in an ordinary shoe.

When ordering braces one may be guided by a descriptive price-list as issued by the well-known firms. As many of the braces for cases of infantile paralysis have to be devised for the individual patient, some practical points are of value. The patient lies on a large square of blank paper, and an outline of the extremity and perhaps the pelvis drawn with pencil. The position of the joints and their exact distance from the sole indicated. The position of the calf, thigh and pelvic bands are outlined with pencil and the exact circumference of the extremity at these points given. The joint at the knee is often omitted or else a lock joint substituted. Artificial muscles of rubber are of no permanent value, as they soon wear out and give trouble. At the ankle, stop joints are often used, according to the presence of talipes or calcaneus. Simplicity and lightness of weight should be in mind while planning the support. The lower end may be attached to the sole of the shoe on the outside or inside, or to a sole plate of metal which is slipped in the shoe. A short description of the patient, his condition, weight, etc., should be added.

The illustration shows a new form of lock joint for the knee, designed by a boy 10 years old, a brother of a patient who had had anterior poliomyelitis. By pressing the handle of the spring at E the pin is moved outward and the joint unlocked, allowing the case to sit comfortably. On arising and extending the leg, the pin slips into the openings made for it through the uprights and the joint is locked. The advantages are simplicity, cheapness and the fact that it does not get out of order.

OPERATIVE TREATMENT.

1. The use of force, either manual or instrumental, followed by a plaster dressing, will usually overcome resistance to passive correction in these cases, because the tissues are not so firm or the deformity so obstinate as in the congenital malformations. Of course, the patient is anesthetized. A succession of plaster casts at rapid intervals, each correcting a little more than the previous will often suffice. Tenotomy is now rarely employed, because tendon transplantation is to be preferred. At the hip tenotomy of the tensor vaginae femoris, sartorius, etc., is the only available operation when the thighs are held in flexion.

11. *Nerve transplantation, nerve grafting or neuroplasty* has come into use during the past eight years, since the time that the distal stump of a paralyzed musculo-spiral nerve was grafted into an intact median nerve with excellent result. Soon followed the successful grafting of the spinal accessory into the facial. The idea of the operation is to restore power in paralyzed muscles by connecting them once more with the spinal cord by functioning nerve fibers. It is applicable in only a few regions, and at a certain time, i. e., after a lapse of time which shows that no further regeneration will take place, in a region where a nerve, or part of a nerve, may be borrowed without doing great damage. In other words, where one set of muscles is paralyzed, part of the power of an adjoining nerve is transferred. It is an operation to precede tendon transplantation and to make that procedure unnecessary. If the nerve grafting fails, as it is supposed to do in about half the cases, then tendon transplantation is resorted to. There are two main types of transference. Peripheral implantation is that method in which the diseased nerve is cut, and its distal stump drawn over and sutured in a longitudinal slit in the healthy nerve, the end pointing centrally. Central implantation is the other type, in which

a part or the whole of a healthy nerve is cut, the central end drawn over to the diseased nerve and sutured in place, the end pointing to the periphery. In this operation eye instruments are used to manipulate the nerves, longitudinal slits instead of transverse ones are made, and longitudinal sutures instead of transverse are inserted in order to avoid bruising and constriction. One or two incisions of sufficient size expose the operative field. The respective nerves are carefully defined and dissected free. The nerve which is to be cut and swung over is divided at such a point that it may be united without tension or traction to the other nerve. That is to say, the free end must be long enough to reach the junction and be sutured without the use of force. The end is inserted in a longitudinal slit, held there by fine longitudinal catgut sutures, and the sheaths may be united also by a few fine silk sutures. Sometimes, instead of a typical central implantation, the diseased nerve may also be completely divided, and the two cut ends, i. e., one end from each nerve, brought directly together and anastomosed, in this way discarding the slit method. The following sites have been used for this operation:

1. For paralysis of the *tibialis anticus*. An incision is made from the head of the fibula downward over the peroneal nerve. Dissection carried through the peroneal muscles reveals the nerve, the several small branches running to the *tibialis anticus*, and the division below into the anterior tibial and musculo-cutaneous nerves. This is the general rule, as dissection shows that the muscle is supplied by separate branches high up, and not by the anterior tibial nerve. These three or four fine branches are cut, close to their origin, brought downward and sewed to the musculo-cutaneous, the ends pointing upward. It is Spiller's advice to take this nerve, as it is more apt to be healthy than the anterior tibial. It is the experience of the writer, in doing these operations on the cadaver, that the one difficult part is the suturing in place of the nerves. Much depends on the accuracy with which this is done.

2. When the entire anterior group is palsied, the anterior tibial may be likewise inserted into the musculo-cutaneous. Or when the peroneal group is affected, the musculo-cutaneous may be sewed to the anterior tibial.

3. At the bend of the knee, part of the external popliteal nerve may be inserted into the internal popliteal for paralysis of the anterior and external groups.

4. In the upper thigh, for paralysis of the quadriceps, the superficial branch of the obturator may be taken to replace the anterior crural. Two incisions are made, one over the femoral artery and the other to the outer side of the tendon of the adductor longus. The anterior crural is easily found and the branch to the sartorius is isolated and held aside, as the sartorius is rarely involved. The obturator is found by separating the adductor longus and pectineus, and defining the nerve as it crosses on the adductor brevis. The obturator is cut low down, to allow length for transposition. The central end is passed through a tunnel over the main vessels, and inserted into the anterior crural, the stub pointing peripherally.

5. At the elbow the distal stump of a paralyzed musculo-spiral may be swung around the elbow and fastened to the median.

6. In the forearm the ulnar, median and radial may be crossed, as seems indicated.²

III. *Tendon transplantation* has for its primary object

2. For the subject of neuroplasty refer to THE JOURNAL A. M. A., Jan. 21, 1905, p. 169; Annals of Surgery, May, 1903; and American Journal of Orthopedic Surgery, Aug., 1904.

the distribution of the remaining power about a joint, so that muscular strength may be exerted in all directions. For example, if the quadriceps at the knee is paralyzed, some of the hamstrings are borrowed to replace it. The secondary object is to use a tendon as a bridle or check rein, to prevent deformity and enable one to dispense with a brace. For example, in a case of paralytic flat-foot, a tendon may be passed through a canal in the navicular bone and fastened there, to hold the arch up and prevent dislocation of the astragalus. This operation is intended to improve conditions only, and must not be considered as a curative measure. It is most effective when one group of the weaker muscles is affected, because a weak muscle can not be made to do the work of a stronger one. For example, the prognosis of a varus or valgus is good, but no transplantation can do the work of the calf muscles, when calcaneus exists. Tendon shortening is included under this heading, i. e., when one overlaps and shortens several tendons about a joint, thus strengthening but not transplanting. Muscle transposition is another form, in which muscle is sewed to muscle. An illustration occurs at the knee, where the sartorius can be inserted into the quadriceps above the patella. Of late there has been a great tendency to add arthrodesis to a transplantation as often as possible, as a stiffened joint may so supplement the advantage gained that a practical cure instead of a relapse will be the result. Many writers now claim that arthrodesis is the main operation and the tendon transplantation is secondary. There is no doubt but that the combined procedures are of great value, especially at the ankle and medio-tarsal joints. Judgment as to the result of the operation should be reserved until some years have elapsed, as cases that promise well at the end of six months may relapse later. It is sometimes astonishing to see how a muscle will hypertrophy and increase in power, when it is given an opportunity to work at advantage with all resistance to passive motion removed. In deciding about an operation and the selection of tendons, one must remember that all cases differ as to the degree of paralysis, and that each case has to be individually studied, and a decision reached according to present conditions. It is not wise to operate until two years have elapsed since the attack, as some power may return in muscles that appear completely atrophied. The writer has seen power reappear to a slight degree, but enough to be of value, as much as eight years after the attack. Before operating, it is a good plan to put on a plaster cast for two weeks to accustom the parts to their new position, and prepare the tendons for transposition. Resistance to passive correction should be overcome by force either before or at the time of operation, so that the plaster dressing need afford fixation only, and not corrective force. The following points are to be borne in mind while operating. Asepsis, prevention of hemorrhage, the use of healthy material and union of tendons under tension. Muscle that has a dark red appearance is healthy, while a yellowish color signifies fatty degeneration. It has been proved that it is best to sew the transferred tendons so that they are slightly on the stretch. They will do better work later on after union is firm, than if they have been fastened without tension.

An Esmarch bandage is applied to provide a bloodless field. One, two or three longitudinal incisions are made over the sites as may be indicated. The tendons to be transposed are dissected free, from their insertion upward for some distance. They are cut at their

insertion, and a temporary suture inserted in their free ends to prevent them from slipping away. By blunt dissection a canal is made, reaching to the point where the tendons are to be attached. This channel should not turn at a right angle, but at an acute angle, so that the tendon will not have to act around a sharp corner. The tendons are drawn through the canal, and then fastened in their new position. Three methods are in common use. They may either be passed through button-holes in other tendons and sewed to them, or better, stitched to the periosteum or passed through a small canal made in the bone, turned backwards and sutured to themselves and to the periosteum. The firmest grip possible is by the last method. A periosteal fixation usually gives a firm hold. The tendons of paralyzed muscles are apt to stretch, like old elastic. If the tendon to be transposed is too short, it may be lengthened by several silk strands. Experiments have proved that there is likely to be a formation of new tendinous tissue along such silk strands which will give a firm grip and a prolongation of the sinews to its new site. Fine silk sutures should be employed, and care taken to appose as much surface as possible that there may be the firmer union. Sterile silk is well borne by these structures as in the peritoneal cavity. The sheaths of the tendons are sewed with fine catgut. The skin is united with catgut and no drainage allowed. Plaster of paris applied for six weeks, removal of this being for dressing only. For a period of at least six months, great care should be taken that no excess of strain is brought to bear on the transposed tendons, and artificial support should be provided. This after-treatment is of chief importance and is the factor which often decides the result. Massage, electricity and medical gymnastics are appropriate aids.

It is a good plan to precede the operation on the patient by the same procedure on the cadaver. Some practical points shown by dissection on the cadaver are the following: The tibialis anticus, when swung over to the cuboid bone, can hardly reach its insertion, and has to be elongated by silk strands. The extensor brevis digitorum overlies the cuboid bone and calcaneo-cuboid joint, and must be drawn to one side in transplantation or arthrodesis. The tendo-Achilles is likewise short, when it is brought to the front of the ankle joint, and must be inserted above the joint. The peroneus brevis reaches the scaphoid bone very nicely when passed back of the ankle. The peronei tendons, posterior to the external malleolus, cross each other, and one must determine by pulling on the tendons, which is which. The tendon sheaths in this locality must be kept as intact as possible, to prevent the unused tendon from dislocation forward over the malleolus. A canal can be bored through a bone in children by a small curved trochar and canula, and then the tendon can be drawn through the canula without injury.

IV. *Arthrodesis* has for its object the artificial stiffening of a joint. It is especially for the poor, as it allows the patient to dispense with apparatus. It is very valuable as an adjuvant in doing a tendon transplantation. The bones must be fairly firm, or, in other words, the child should be 8 or 10 years old before it is attempted. The foot is its especial province. The ankle joint is stiffened for equinus or calcaneus, and the medio-tarsal joint for varus or valgus. Opinion is divided about the knee joint as to the advisability of making the lower extremity stiff throughout, when a fall might fracture one of the bones, brittle from trophic changes. The operation has been performed at the shoulder.

An Esmarch bandage is applied. An incision exposes the joint, which is opened. All of the cartilage is removed and the bone laid bare, by spoon, or by the use of chisel and hammer. Some operators remove a thin slice of bone to entirely eradicate the cartilage cells, which, by reproduction, would favor return of motion. The soft parts are sutured with catgut, and a plaster dressing applied. Strain must be avoided for six months or more, as after transplantation. In old cases of calcaneus, astragalectomy is more serviceable than arthrodesis.

V. Linear osteotomy or cuneiform osteotomy are too well known to require a special description. They are sometimes indicated at the tarsus, knee or hip in severe cases.

In closing, emphasis is laid on the fact that the results of infantile paralysis are of a mechanical nature. It is often possible to predict what deformity will ensue, according to the groups of muscles involved. The general practitioner has a duty to perform which has been too much neglected in the past, i. e., to prevent deformity. Each case differs from the others in the area involved and the severity of the paralysis. The treatment for the individual patient should be instituted only after a careful examination to determine what is indicated. The great tendency, of late years, has been to operate more often and to dispense with apparatus. The instrument maker is no fit person to have charge of such cases. Patients must be watched for years, at intervals of six months, because conditions change and vicious habits may be adopted.

DISORDERS FROM EYE-STRAIN.*

OVIDUS ARTHUR GRIFFIN, B.S., M.D.

Examining Eye and Ear Surgeon, U. S. Bureau of Pensions.

ANN ARBOR, MICHIGAN.

Notwithstanding that much has been presented on this subject, it is a lamentable fact that a large percentage of the medical profession fail to appreciate the nature and consequences of eye-strain. Thousands of patients are annually being subjected to a medicinal treatment of reflex disorders, arising from eye-strain, while the etiologic ocular defect remains unappreciated by both the patient and his attending physician. Fortunately, this state of affairs does not obtain throughout the profession. Scattered here and there, like oases in a desert, are physicians who, having personally suffered (like the writer) from the torture of ocular defects or intelligently observed them among their clientele, are appreciative of their significance and rational treatment. When it is learned on investigation, however, that a large majority of text-books and monographs on internal and nervous disorders are silent as to the importance of eye-strain in the production of certain neuro-gastric diseases, it is small wonder that the etiologic ocular defect is so often unappreciated by the general practitioner in the treatment of these disorders.

The usual symptoms of eye-strain may, for the sake of brevity, be grouped under three headings: Phenomena of (a) muscular asthenopia, (b) conjunctival and retinal irritation, (c) defective vision. With the former condition the patient complains of pain or pulling sensation within the orbital cavity, temporal or frontal regions, or within the eyeball itself, which is due to an abnormal tension of either the extraocular or ciliary

muscles or both. With irritation of the conjunctiva, however, the eyeball and lids become injected, aggravating any existing acute or chronic inflammation of the lids, and attended with a hyperlachrymation which may be so pronounced as to simulate epiphoria due to stenosis of the lachrymal duct. The symptoms of asthenopia, irritation and blurring of vision may obtain constantly or only on doing near work, but are usually accentuated by a close application of the eyes, e. g., sewing or reading. Aside from myopia, normality of sight does not exclude the existence of refractive errors, especially the more moderate degrees of hypermetropia and astigmatic conditions, particularly in the young who enjoy the necessary accommodative power to overcome the defect. With the advent of presbyopia, however, when the accommodation becomes physiologically impaired, the refractive error usually becomes manifest with an attending lowered distant vision. So far as symptoms are concerned, furthermore, it is impossible to differentiate an imbalance of the extra-ocular muscles from an error of refraction, excepting when an extra-ocular muscle becomes so weakened that it can no longer cope with its opponent, when a diplopia occurs or it is corrected by an inclination of the head. Sensations of dizziness and nausea frequently obtain as a result of these conditions, although they may also be produced by astigmatic conditions, particularly when the axes exist at oblique angles.

The normal eye often tires with a physiologic amount of work, but when a prolonged effort is made to employ a defective visual apparatus the task becomes not only unpleasant, but oftentimes distressing to a marked degree with more or less reflex disturbances, depending on the nature and extent of the ocular defect, together with the systemic condition of the individual. Hence, a muscular or refractive defect which produces few or no symptoms in one instance may so affect the health of another person that a serious impairment of the vital functions occurs. The heart, which we are wont to regard as unceasing in its work, enjoys a longer period of rest than activity, but in instances of eye-strain the correcting muscles are under a constant tension during all the hours of visual activity. So long as there obtains a sufficiency of reserve force to supply this continued expenditure of nervous energy, the symptoms are latent, but finally in many instances an exhaustion occurs, accompanied by manifestations of a varied symptomatology.

It is to the importance of these systemic disturbances resulting from eye-strain, therefore, that I wish specially to direct attention. As previously indicated, these disorders are so varied, complex, and oftentimes pronounced that the symptoms of the causal ocular defect are quite unappreciated, in many instances, by both the patient and his attending physician, until by accident or design the etiologic condition is recognized and corrected. Thus it is that the ophthalmologist frequently meets with instances of chronic headache, gastric disorders, nervous exhaustion, insomnia, epilepsy, chorea and hysterical conditions which have resulted wholly from eye-strain, and continued in spite of the medicinal treatment which has been so erroneously employed, but have obtained permanent relief after the correction of an ocular defect.

To illustrate briefly the validity of my contentions in this direction, I append a few characteristic instances of reflex disorders which have often been encountered in my practice as an ophthalmologist:

CASE 1.—Mrs. H. W. W., aged 35, presented the following history: Since childhood she has suffered from nearly constant headaches and a nervous condition, although she has

* Read before the Michigan State Medical Society at Petoskey, June 28, 1905.

employed the advice of several physicians with no relief. She finally concluded that trouble originated in her eyes, inasmuch as near work increased her symptoms, and consulted a prominent oculist, who gave her the following lenses for constant use: O. D. +.50 +.25 x 90, O. S. +.75 x 90. Obtaining only partial improvement, she finally consulted me, when an examination of the eyes revealed the following refractive condition: O. D. —.25 +.75 x 90, O. S. —.37 +.88 x 90. Since wearing this correction she has enjoyed a complete cessation of headache and a gradual improvement in general physical condition during the past two years without the use of internal medication.

CASE 2.—Miss G. M., aged 30, for several years has complained of constant and intense headaches, pain in eyes, and nervous symptoms. Has received medicinal treatment from several physicians without avail. An examination of eyes showed the following conditions: O. D. +.50, O. S. +.25 +.25 x 90. Right hyperphoria 2° (tendency of right eye to turn upward). Glasses were prescribed to be worn constantly, with which the muscular imbalance was corrected as well as the refractive defect. During the following year she informed me that the former symptoms had entirely disappeared, but a year later the symptoms began to return, when an examination showed that the hyperphoria had increased to 4°, for the permanent correction of which I advised a graduated tenotomy, but this was declined, so the former prismatic correction was increased to meet the condition, since which time she has not come under observation.

CASE 3.—Mr. P. B. J., aged 25, presented history as follows: For several years he has complained of constant dull frontal and occipital headaches, pains within the orbit, loss in weight, and pronounced nervous symptoms which were increased by a prolonged use of the eyes. Riding on the cars, attending the theater, or watching rapidly moving objects invariably increased the above symptoms, attended with a sensation of nausea. He had employed the advice of several general practitioners, without permanent relief. Was wearing O. U. +.50 sph. An examination of the eyes revealed the following conditions: O. U. +.50 x 90, and 12° of esophoria (tendency of eyes to turn inward). Advised a graduated tenotomy of both internal recti, which was accordingly performed, leaving but 1° of imbalance of muscles. So great was the relief afforded by the operation and correction of the astigmatism that the patient was enabled to follow with comfort his clerical work, and rapidly gained in vigor and weight, without the aid of medication.

CASE 4.—Mr. G. S. M., aged 31, consulted me, presenting the following history: Marked headaches, neurasthenia, a growing insomnia, and gastric disorders. During the previous ten years he had consulted several general practitioners and oculists regarding his condition, but had obtained no permanent improvement. To account for the symptoms one physician informed him that he had "congestion of the brain," while an equally mistaken prominent oculist corroborated this diagnosis because a "retinitis" was found to exist! Examination of his ocular condition revealed to me the following conditions: O. D. +.25 +.25 x 90, O. S. +.50, and 18° of esophoria. When I informed him that, in my opinion, his condition was due largely, if not wholly, to the imbalance of his extraocular muscles, he was astonished, as none of his medical advisors had suspected or made a test for heterophoria (imbalance of eyes). I advised a graduated tenotomy of both of his internal recti, which was performed. Although previous to the operation and wearing of correction for his refractive error, he was particularly distressed by insomnia, during the past two years he has frequently expressed his gratitude for the great relief afforded him; and is now carrying on his multitudinous duties with satisfaction.

CASE 5.—Mrs. M. S. W., aged 35, presented the following history: Since childhood she has been subject to periodical headaches, which she regarded as hereditary, inasmuch as her mother and an aunt had suffered similarly without relief. During the past few years she has complained of heart trouble, dyspepsia, marked constipation, and periods of extreme nervousness. While suffering from an attack of headache an uncontrollable nausea and vomiting would occur which so ex-

hausted her strength that she was often compelled to keep her bed for several days. Several physicians had been consulted regarding her condition, but no permanent relief was obtained. Finally her refractive symptoms became so evident that she was led to consult me regarding her ocular defect. Examination of eyes revealed the following facts: O. D. —1.00 +.25 x 60, O. S. —.75 +.25 x 120. Normal balance of extraocular muscles. The above correction was prescribed to be worn constantly. Although she experienced in the beginning some difficulty in wearing the glasses, she soon became accustomed to them; and although several years have elapsed since this defect was corrected, she has enjoyed a complete cessation of her former distressing symptoms.

CASE 6.—Mr. J. R., aged 43, a man of broad scientific attainments, presented the following history: During the past ten years he has suffered frequently from periods of nervous exhaustion, gastric disorders, constipation, and a marked insomnia, which of late had become more pronounced in spite of the advice and treatment of several physicians. He had concluded that possibly his symptoms might originate from an eyestrain, and accordingly consulted me in regard to his condition. An examination of the eyes showed the following conditions: O. D. +1.00 +.25 x 180, O. S. +.75 +.25 x 180, and 1° of left hyperphoria and 2° of exophoria (tendency of eyes to turn outward). Glasses were prescribed to be worn constantly, correcting both the refractive and hyperphoric conditions, while prismatic exercise was advised for improvement of the weakened internal recti. A marked betterment in both the ocular and systemic disorders was obtained thereby, but a couple of months later he again consulted me, stating that he was still conscious of some strain in the use of his eyes. A further test of his condition revealed the fact that the hyperphoria had increased another degree while the exophoria had disappeared. Being persuaded that my patient was suffering from a latent hyperphoria, the prismatic correction in his glasses was gradually increased until the imbalance became stationary at 4°, when I advised a graduated tenotomy of the left superior rectus to permanently correct the defect. At a subsequent date the operation was performed, leaving only $\frac{1}{2}$ ° of hyperphoria, while the lateral recti were in balance. The cessation of his former systemic symptoms under this treatment was interesting and gratifying, both to the patient and myself. While previous to the correction of his ocular defect he was confined strictly to a simple diet of bread and milk and suffered greatly from his insomnia, in the course of a few weeks he was able to relish an ordinary mixed meal, his bowels became more regular, the insomnia disappeared, and a rapid increase in weight was observed.

CASE 7.—Mr. M. H. G., aged 28, presented the following history: During the past ten years he has been suffering from headaches, gastric disorders, and nervous symptoms, attended with a marked loss of weight. While in college some six years ago his symptoms became so marked that he was compelled to abandon his work. He placed himself under the care of several physicians, but obtained no relief until by accident he learned from a fellow-student, who had suffered a similar experience, that possibly his physical condition was due to an ocular defect. He accordingly consulted a prominent oculist, who gave him for reading O. U. +1.00 +.50 x 90, from the use of which he obtained some relief. After wearing this glass for four years he came under my care, and an examination of his eyes showed the following conditions: O. D. +.25 +1.00 x 90, O. S. +.37 +1.00 x 90, and a slight exophoria. He was instructed to wear his correction constantly, since which time his symptoms have entirely disappeared, and he is in robust physical condition. No medication has been employed by him since wearing this correction.

CASE 8.—Mr. C. A. H., aged 26, gave the following history: Previous to entering college he had passed the greater part of his life in out-of-door pursuits, but during the past two years, since devoting himself to study, his health has gradually failed until now he complains of a drawing sensation about the head, dizziness, gastric disorder, and a marked nervous condition. No definite refractive symptoms were noticed in use of eyes. He has consulted several physicians without obtaining permanent improvement. Examination of eyes showed the following

conditions: O. D. +.25 +.62 x 90, O. S. +.25 +.50 x 90, and 3° of exophoria. Prescribed above glasses to be worn constantly, in addition to which I advised employment of prismatic exercise for the improvement of his weakened internal recti. Within one month he noticed a marked betterment in his physical condition, which, without the use of internal remedies, continued to so improve that he was finally enabled to pursue his professional course of study with satisfaction.

CASE 9.—Miss E. S., aged 16, presented a history as follows: Since 6 years of age has had indistinct vision for distance and difficulty in reading which has gradually become worse, attended with a rolling of eyes, twitching of lids, spasmodic contortions of the face and shoulders, and an increasing nervous irritability. Examination of the eyes revealed the following conditions: O. D. — 3.00 — 1.50 x 180, O. S. — 3.00 — 2.00 x 180, and 1° of left hyperphoria. She was instructed to wear the above correction constantly whereby the muscular imbalance was also remedied by decentration of left lens. In the course of a year, without the use of any medication, the above symptoms practically disappeared and she gained markedly in weight. Two years later, however, she began to notice an irritation of the eyes, a blurring of distant vision, and some twitching about the eyes. Examination showed the following conditions: O. D. — 4.00 — 1.25 x 180, O. S. — 4.00 — 2.25 x 180, and 3° of left hyperphoria instead of above. With the correction of these defects the symptoms again disappeared in the course of a few months.

CASE 10.—Mr. C. L. C., aged 28, gave the following history: During the past five years he has complained of a pulling sensation in his eyes, feeling of constriction about the head, gastric disorder, loss of weight, and a marked nervous exhaustion, which finally terminated in an acute attack of melancholia. During the past six months he has been unable to use his eyes for ordinary reading. An examination of his ocular condition revealed the following: O. D. + 3.00 + .88 x 90, O. S. + 2.00 + .75 x 90, and 4° of esophoria. A partial correction was prescribed for constant use, and gradually increased until he was able to employ the full correction. In the course of a few months his former symptoms practically disappeared, and he was enabled to carry on his former occupation with satisfaction. Occasionally he would notice a return of some of his symptoms; but these were readily traced to a malposition of his lenses, due to a bending of his frame, on the correction of which the symptoms would disappear.

In conclusion, I wish to emphasize the fact that the foregoing illustrative cases of eye-strain are not rare in occurrence nor are the reported favorable results of ocular treatment exceptional, but they are frequently being encountered and successfully treated by those ophthalmologists who are doing thorough, scientific and conscientious refractive work. In contradistinction to these facts, however, I am sorry to admit that there is an alarming amount of humbuggery practiced in the "fitting of glasses." In making several thousand examinations of the eyes I have found that over 90 per cent. of refractive errors are astigmatic, one-quarter of a diopter or more, while 50 per cent. of the lenses prescribed from various sources are merely spherical. In other words, probably 75 per cent. of the glasses worn to-day do not accurately correct the ocular defects of the wearer, not taking into consideration muscular imbalances. When it is remembered, however, that the greater percentage of these glasses are furnished by pseudo-specialists, "jewelers and opticians," "optical specialists," "doctors of optics," "optical companies" and quacks in general, whose chief equipment consists of gross pretensions, commercial aggressiveness and the ubiquitous sign:

EYES EXAMINED FREE,

whereby the gullible and credulous are led to believe that they will receive something for nothing, it is small wonder, indeed, that the anticipated results of

ocular treatment are so frequently unrealized and that the uninformed laity and indiscriminating physician often confuse the claims of the ophthalmologist with those of the pseudo-specialist.

It is gratifying to note, however, that during the past few years an increasing interest and broader knowledge has been exhibited by the medical profession in the diagnosis and rational treatment of eye-strain. Even in the conservative medical centers of Europe, as I recently learned in an extended tour of her hospitals, considerable importance is being attached to ocular defects in the production of neuro-gastric disorders, but there is plenty of room for improvement in this direction, both at home and abroad.

AN ANALYTIC STUDY OF UREMIA.

WITH SOME GENERAL CONCLUSIONS IN REGARD TO ITS CAUSES AND TREATMENT.*

ALFRED C. CROFTAN, M.D.

CHICAGO.

CRITIQUE OF CURRENT UREMIA THEORIES.

If the current belief that uremia is due to renal inadequacy and the retention in the blood and tissues of excrementitious urinary bodies were correct, then (1) complete anuria should always produce uremia, and (2) the blood of uremic patients should always show an increase and the urine a corresponding decrease of urinary substances.

Anuria Without Uremia.—Many cases of complete anuria, due to various causes, are, however, recorded, in some instances persisting for several weeks, in which none of the characteristic phenomena of uremia developed. Most of these patients for days complained of nothing more than a feeling of extreme lassitude, death resulting suddenly from heart failure without preceding coma or amaurosis, and without eclamptic spasms or typical changes of the blood pressure. On the other hand, uremia not infrequently occurs when the flow of urine is abundant and the excretion of urinary solids and water does not appreciably deviate from the normal.

Similar results are seen in animals after experimental nephrectomy or occlusion of both ureters. The animals die, but not uremic.

Uremia and Urinemia.—Death produced in animals by the injection of urine also produces a syndrome that differs materially from the uremic symptom complex. One must, therefore, distinguish clinically between uremia and urinemia. In uremia we often, but not invariably witness many of the signs of urinemia, but also many other signs besides. These other signs are the most constant and the most characteristic symptoms of uremia and the fact that they do not occur in urinemia forces one to the conclusion that they must be produced by other factors than simple urine poisoning. This view is borne out by a study of the solids of the blood and urine in uremia.

1. *The Nitrogenous Constituents.*—With the recent refinement of chemical technic these bodies (comprising chiefly urica, uric acid and its chemical congeners, the purin bases, ammonia salts, amido acids, creatin and others) have been diligently studied. The accumulated material is enormous, but disorderly. A careful sifting of the analytic data leads to a negation of the retention theory of uremia.

* This is a preliminary synopsis, full analytic data and clinical protocols will be published later.

For we see (1) as many cases of uremia develop without as with an abnormal accumulation of nitrogenous constituents in the blood; (2) we find uremia when the nitrogenous waste products of the blood are below the normal average, and (3) we inversely often fail to witness the appearance of uremia when the accumulation of these products in the blood is high above normal.

Similar conditions are determinable in the urine. Uremia may develop when (1) the patient is in nitrogen equilibrium (i. e., when the nitrogen output corresponds to the nitrogen intake) or (2) when the nitrogen output is far above normal, or (3) when the nitrogen output is below the normal average as compared to the intake; but it does not appear from a careful sifting of the analytic data published (including also some unpublished studies of my own) that uremia is more common when the nitrogen output is reduced below normal than when it is normal or even increased. Finally, many cases of true nitrogen retention are on record in which uremia failed to occur.

A quantitative study of the circulating and excrementitious urinary nitrogen bodies, therefore, teaches practically nothing of the causes of uremia. Only when we determine separately the various groups of nitrogen bodies that occur in the blood and the urine do we encounter certain deviations from the normal that may be considered fairly characteristic. I refer chiefly to two findings, viz.: (1) A relative increase of the ammonia salts, both of the blood and the urine as compared to normal average values, and as compared to the circulating and excrementitious urea. (2) A relative decrease of the urea both of the blood and urine as compared to average normal values and to the total nitrogen contained in circulating and excrementitious nitrogenous waste products.

These two findings I consider to be of the greatest importance, as I will have occasion to show.

It is well to bear in mind that there may be present in minute quantities among the nitrogen bodies of the blood and urine certain highly toxic albuminoid or alkaloid bodies that might produce an enormous effect without appreciably changing the nitrogen content of the blood and urine nor the relative proportion of the better known nitrogenous constituents to one another. This point also will be referred to again.

II. *The Inorganic Saline Constituents.* In the case of the salts of the blood and the urine our data are for the most part obtained from physical methods of examination, viz., cryoscopy and electric conductivity tests, determinations that are far more accurate than chemical methods of analysis. The electric conductivity in particular is a function of the salt content (molecular concentration) alone of the blood and urine and is altogether independent of the nitrogenous bodies that may be circulating at the same time; hence this latter method gives us especially valuable information in regard to the salt economy of the body in uremia. The slight inaccuracies inherent even in these physical methods are, I believe, overbalanced by the mass of figures collected in each case, for the technic when once properly acquired is so simple and rapid of execution that the operator is enabled to perform a great many determinations in the same patient within a short time.

The collected data show a marked degree of uniformity and indicate clearly two things: (1) That uremia often occurs when the salt values in the blood are normal or under normal; (2) that uremia need not occur even when the increase of salts in the blood and the corresponding decrease in the urine are very marked.

It appears, in other words, that increased molecular concentration of the blood is by no means a constant phenomenon in uremia. (This refutes Lindemann's seductive "physical" theory of uremia.) There is, in fact, less numerical evidence to show that uremia is due to salt retention than to the retention of nitrogenous waste products. One might argue again as in the case of the latter that certain salts were exclusively toxic and were present in such minute quantities that they might poison the patient without appreciably altering the molecular concentration of the blood; this postulate can not be absolutely negated by the evidence at hand; but if such salts play a commanding rôle in uremia (one might think for instance of cyanids) then they are not identical with any of the salts that normally appear in the urine, for none of the latter can exercise a pronounced toxic effect in quantities that would be so small as to escape detection by the chemical methods that are being employed to look for them.

This applies in particular to the potassium salts of the urine that have so often been accused of producing uremia. True, these salts are poisonous and they undoubtedly play an important part in urinemia (presumably causing death in this affliction by their action on the heart), but they can not be incriminated with causing the characteristic symptoms of uremia. Thus we are forced to the conclusion that neither the retention of the nitrogenous bodies nor of the salts that normally occur in the urine generally produces uremia. So much for the negative side of the argument.

The questions now arise: (1) What is the character and the origin of the poisons that can be accused of producing uremia? (2) What function or functions must become perverted; what organs (if not the kidneys) must become diseased in order that these poisons may be formed? For poisons there must be, as no one will gainsay.

THE CAUSES OF UREMIA.

It is well known that in uremia the urea secretion is often decreased; this fact is commonly interpreted to signify that the elimination of this body has become deficient, in other words, that it is being retained. If its elimination, however, were merely interfered with, it should always be correspondingly increased in the blood, and this is not the case.

I am inclined to the belief that the decreased urea secretion is not so much due to retention as to non-formation. This postulate is borne out by the finding referred to in a preceding paragraph, viz.: That with a decrease of the urea in the urine and blood, we very often find an increase of the ammonia. This points to the liver as the affected organ, for the bulk of the circulating ammonia is normally converted into urea in the liver.

There is other chemical evidence that points to the liver as the deranged organ. I refer, e. g., to the occasional increase of the purin base excretion relative to the uric acid excretion (the purin bases forming a precursor of uric acid that should normally be converted into the latter in the liver), and the increase of uric acid relative to urea (the former being a precursor of the latter, the conversion also occurring in the liver), the appearance of various amido-acid compounds, and compound glyconates; of members of the acetone body group in uremia. The reduced tolerance for carbohydrates with alimentary glycosuria that I have noticed in several cases of chronic uremia also seems to point to some liver derangement.

All this chemical evidence that supports the idea of an hepatic instead of a renal origin of uremia is somewhat scanty; and our knowledge of the normal intermediary metabolism within the liver is at best still so deficient that we must approach the interpretation of its perversions with much trepidation. The clinical evidence, however, and what may be called the pathogenetic evidence in favor of the hepatic origin of many cases of uremia is in my judgment very strong and very convincing. For we know clinically that disturbances of the liver and of the kidneys often go hand in hand and I believe we would find this to be still more frequently the case if the liver were examined with the same degree of thoroughness as the kidneys in each case of nephritis or of Bright's disease that came to autopsy; and if mild, functional disorders of the liver were as easily recognizable as those produced by renal disorders of like severity.

That the liver, i. e., hepatic insufficiency, plays an important rôle in the pathogenesis of Bright's disease is acknowledged¹; that, further, the same infectious or toxic agencies that produce nephritis also affect the liver in most cases is clear. For to the liver and to the kidneys jointly is relegated the rôle of ridding the organism of toxins, the former eliminating them into the bowel by the bile, the latter into the bladder by the urine. Toxins, moreover, of gastroenteric origin (and they constitute the most important of the exogenous poisons) must pass through the liver to reach the general circulation and the kidneys beyond. The same applies to poisons derived from metabolic perversions (endogenous poisons) for they are either for the most part generated in the liver or are carried to it before they reach the kidneys.

Assuming now for the sake of argument that the kidneys were always primarily affected in cases that ultimately determine towards uremia, so that their power of eliminating circulating toxins were diminished, then the bulk of the disintoxicating function would be thrown on the liver and in time hepatic insufficiency, i. e., overtaxation, fatigue of the liver cells, would develop. The character of the hepatic lesion would depend in each case on the virulence of the circulating toxins and the length of time during which they circulated.

There is still another idea that must be considered in this connection. It may be called the defective filter idea. It is a well-known fact that nephritic kidneys, while on the one hand less permeable than normal kidneys for a variety of circulating bodies, are on the other hand more permeable than normal for certain other bodies. In the case of the kidneys we are dealing with a living selective filter that is intended to hold back certain substances that are still useful to the organism and to allow the passage of other compounds that have outlived their usefulness, that possess no more potential energy, that are completely oxidized, dead, more ash, and that should be gotten rid of as soon as possible.

When the kidneys are diseased, the filter leaks. Useful bodies that could still furnish a modicum of heat and energy are wasted. Among such bodies many are nitrogenous derivatives of albumin, as ammonia salts, amido acids, etc., bodies that should normally have been carried back to the liver for further elaboration to terminal products, like urea, uric acid, etc. When

such suboxidized nitrogenous compounds are wasted, the body, we must assume, is forced to disintegrate more of albuminous pabulum in order to make up the deficit and the bulk of this additional labor is thrown on the liver. In time, this organ must consequently become fatigued, so that the further disintegration of albumins either proceeds more slowly than normal or becomes altogether perverted into abnormal channels.

When this happens less urea and more incompletely dissimilated intermediary products of albuminous metabolism are thrown into the circulation; or bodies are split off from the albumin molecules that are completely foreign to normal blood and that are poisonous. Substances of this character are actually found in the blood of uremic cases.

One may further say axiomatically that the less complete the dissimilation of the albumins the more do the generated products maintain an albuminoid character (ptoma peptones, peptotoxins), and the more intensely toxic do they become.

That the general metabolism of albumins in particular is perverted in uremia is further manifested by the frequent appearance of acidosis in terminal uremia and even in pre-uremic states; in fact, an acid intoxication must be incriminated with producing many of the fulminating signs of uremic, as well as of diabetic, coma. The increased excretion of ammonia that has been referred to may even be explained on the basis of a chronic acidosis, for we know that ammonia is thrown into the circulation whenever abnormal amounts of acids begin to circulate. This is a protective process, inasmuch as it aids in maintaining the normal alkalinity of the body fluids and the alkali content of the cells. The ammonia salts formed in this way are sacrificed at the cost of urea; hence more ammonia and less urea in the blood and urine of uremic cases. As urea is the most potent physiologic diuretic the flow of urine is at the same time often reduced.

This in rough outline is the pathogenesis of a self-intoxication, either acute or chronic, that may follow or accompany chronic renal disease, and still be due more to hepatic than to renal inadequacy. That the liver is not the only organ affected is probable, and uremia interpreted as above is not so much the result of hepatic derangement alone as of a general metabolic disturbance. This view is forcibly borne out by the observation of an occasional case of uremia, in which the kidneys are found practically normal after death, and in which essentially no evidence of renal disease or even of functional inadequacy on the part of the kidneys presented itself during the life of the patient.

The manifold factors that may precipitate an acute attack of uremia in an individual suffering from hepatic insufficiency (pre-uremia) need not be enumerated in detail; the determining insult may be severe as, for instance, some virulent infection or intoxication (chloroform anesthesia) suddenly throwing a mass of work on the liver or causing degeneration of its cells, or it may be apparently insignificant, and consist of nothing more than an attack of gastric or enteric indigestion or merely some psychic or emotional shock that acutely deranges the liver function.

How important it is, therefore, to be able to recognize early even mild degrees of hepatic insufficiency (particularly in renal cases and in pregnant women), and to safeguard the patient against all the agencies that might suddenly throw a strain on the fatigued liver!

¹ Croftan: "The Circumstances and Treatment of Bright's Disease," *THE JOURNAL A. M. A.*, June 24, 1905.

GENERAL PRINCIPLES GOVERNING THE TREATMENT OF UREMIA.

We are wont to treat uremia by stimulating the flow of urine, by purging and by sweating, with the intention of forcing the kidneys to resume their work, and of ridding the body of the urinary bodies that we imagine to be circulating in excess. In addition, we attempt to regulate the diet in such a way that there shall accumulate in the blood the smallest possible amount of residual nitrogenous bodies ("Harnschlacken"). If, now, uremia is not due to the circulation in excess of such bodies, the above therapy is wrongly directed.

It is questionable, moreover, whether any of the above measures can at best do more than rid the body of water, some sodium chlorid and possibly a little urea; the loss of water one might imagine to do more harm than good, for it should promote the concentration of the poisoned body fluids, and hence render them more toxic. There is surely no exact evidence to show that the sweat or the urine of uremic cases after the use of diaphoretics and diuretics becomes more toxic than before; nor has any one ever succeeded in demonstrating in such sweat or urine any of the albuminoid or alkaloid bodies that must be accused of causing the most fulminating symptoms of uremia.

The chief object of treatment should be to prevent the development of acute uremia by giving attention to those organs and functions that threaten to fail. In order to do this intelligently, the renal idea should be relegated to the background, and more attention should be bestowed in pre-uremic states on the liver and the general metabolism. The liver, above all, should have a rest. To stimulate the liver in chronic uremia is bad practice. The same principles should obtain here as in the treatment of a fatigued heart or a fatigued stomach or a fatigued nervous system.

First rest, then graduated exercise until the normal tone is regained. Stimulation should be reserved for emergencies and as a last resort. To accomplish this end all articles should at first be eliminated from the diet that can irritate the liver or stimulate it to increased functional activity; every effort should be made to reduce intestinal putrefaction to a minimum, for intestinal toxins as they reach the liver severely strain the disintoxicating function of the organ. No cholagogues should be administered.

After a period of rest—and starvation for a few days seems a rational plan—the liver may be gently stimulated in the hope that it may be coaxed gradually to resume its functions. This should be attempted by the carefully graded administration of salicylates, of bile acids, possibly of calomel; in addition, various dietetic and physical means may be adopted that we know to be capable of stimulating the various functions of the liver. All this treatment should be carried on with careful supervision and daily control of the effect of these measures on the functional activities of the liver as evidenced by the composition of the stools and the urine and the general condition of the patient. The details of the various means mentioned and of the symptomatic evidences of the state of the liver function can not be discussed within the narrow frame of this article. I content myself with establishing general principles.

The treatment of the acute uremic attack is always an ungrateful task; for it is immaterial whether we are dealing with a disorder that is primarily or in its ultimate consequences due to renal or hepatic or general

metabolic insufficiency, in any case we are dealing with a terminal syndrome, that is due to the crumbling of the whole cellular edifice. To arrest this collapse, essentially means to revive a dying organism. That this may occasionally be done for the time being can not be denied; and as the recuperative powers of the human body border on the phenomenal no effort should be spared to bring an acutely uremic patient back to life.

Of sweating, purging and the stimulation of the kidneys I have already spoken. The administration of liver stimulants by mouth seems hardly feasible, and I have never seen any good effects in uremia that I could fairly attribute to this practice. The most sensible procedure is blood-letting. This useful measure constitutes a lost art nowadays, and it is time that it should be revived; we are dealing in uremia with a toxemia (for no organic lesions that could explain uremia are discovered after death), and to eliminate some of the poisons that are present in the blood by bleeding is always indicated; whether the injection of a saline to replace the lost fluid is useful or necessary is not yet established; it can certainly do no harm, particularly if some saline is injected that can stimulate the hepatic function, e. g., salicylate of soda in normal salt, or a solution of sodium citrate or phosphate in appropriate molecular concentration. Symptomatically, the use of such infusions has been useful in my hands, and has occasionally caused the most alarming symptoms of an uremic attack to disappear when other measures, I think, would have failed.

A CASE OF TRAUMATIC ANEURISM OF THE RIGHT RENAL ARTERY, WITH A REVIEW OF THE LITERATURE.

PENN-GASKELL SKILLERN, JR., M.D.

Assistant Demonstrator of Normal Histology in the University of Pennsylvania; Assistant Physician to the Dispensary for Women of the German Hospital; Assistant Surgeon to the Dispensary for Genito-Urinary Diseases, University Hospital.

PHILADELPHIA.

Because of its rarity and the few cases that have been successfully operated on, I report this case of traumatic aneurism of the right renal artery that occurred during my service as house surgeon at the German Hospital. This patient was operated on by Dr. John B. Deaver, with whose permission I present the report:

History.—J. D., male, aged 26, single, machinist, was admitted to the surgical wards of the German Hospital March 17, 1905. There is no hemophilic, tubercular, neoplastic, cardiac or nephritic history in the family. The man smokes constantly and has used alcoholic beverages freely until lately. He denies venereal history. His appetite has been variable; bowels have usually been regular.

Present Illness.—When 12 years of age he was thrown from a horse and landed heavily on the ground, the brunt of the blow being received in the right lumbar region. The patient went to bed on account of shock, and complained of sharp, cutting pain in the right lumbar region, followed by hematuria. There was no vomiting. After being confined to bed for about twenty-four hours, the patient got up and went about his business. About a month after the accident he was seized again with a sharp, cutting pain in the right lumbar region, which lasted about two hours. He has had similar attacks of pain, usually with intervals of five days; often six months would elapse without any symptoms whatsoever. Each attack was severer than its predecessor.

The patient has never vomited, except after a hypodermatically injected dose of morphin; has never passed a calculus; he has never had a chill during an attack; he has never had a protracted cough, nor has he noticed any loss of weight. He was never jaundiced and never passed a gallstone.

The present attack began suddenly four days before admission to the hospital, with a colicky pain in the right lumbar region, which was referred down along the course of the right ureter to the end of the penis. Two days before admission he passed a moderate amount of blood through the urethra. This is the third attack in which blood was so passed.

Examination.—The patient was found to be of medium size and well nourished. Careful examination of the body revealed no pathologic condition, except that in the right lumbar region, where there was a moderate degree of bulging of the walls of the ilio-costal space, together with tenderness and pain rigidity.

There was a fixed tumor laterally between the ninth rib above and the iliac crest below, posteriorly reaching the right erector spinae muscle, and anteriorly extending to a point 3 cm. external to the right linea semilunaris. Dullness was obtained over this area. The tumor was apparently cystic. No thrill or expansile pulsation could be felt, nor could a bruit be heard. The area of liver dullness showed a displacement of the liver upward for about 4 cm.

Blood Examination: Hemoglobin, 60 per cent.; red blood cells, 2,790,000; white blood cells, 11,700; color index, 1.0.

Urine Examination: Total amount in twenty-four hours, 620 c.c.; color, dark brownish-red; reaction, acid; sp. gr., 1.029; albumin, trace; glucose absent; urea, 2 per cent. Microscopically, abundant red blood cells, epithelial cells, phosphates and leucocytes were seen. No tubercle bacilli were found.

Diagnosis.—The history of a fall from a horse, landing on the right side, followed by pain in the right lumbar region and by hematuria, with moderate disability, suggested trauma of the kidney. The subsequent history of periodical attacks of pain, several of which were accompanied by hematuria, and the presence of a yielding tumor led us to suspect a hematonephrosis.

No signs were elicited that would reveal the presence of an aneurism. The duration of the condition, fourteen years, taken in conjunction with the negative family history, the absence of metastases or of cachexia, and the very moderate constitutional disturbances, led us to exclude malignancy, the secondary anemia present being accounted for sufficiently by the latest hemorrhage. Hydronephrosis was also excluded. So, too, the history and findings of the case made the presence of a renal calculus an improbability.

Operation.—The patient was etherized and the operation performed by Dr. Deaver on March 18, 1905.

An oblique incision 10 cm. in length was made in the right ilio-costal space, and the peritoneal fat exposed. The right kidney was palpated and found to be enlarged sufficiently to warrant an extension of the incision anteriorly about 7.5 cm., carefully avoiding the peritoneum. While attempting to deliver the kidney, its lower pole ruptured, allowing about 200 c.c. of partly clotted blood to escape. The ureter was clamped and ligated. The kidney was delivered by successively clamping and cutting the adhesions surrounding it. The renal artery was palpated and found to be 1.5 cm. in diameter and the site of a tubulated aneurism. It was clamped close to the aorta and opened distal to the clamp, permitting the escape of fresh blood. The renal vein also was clamped. In freeing the upper pole of the kidney it was found necessary to go as high up as the ninth rib. The kidney was removed, but that part of the renal artery between the clamp and the pelvis of the kidney was left in place. Oozing from the bed of the kidney was controlled by a piece of iodoform gauze; four clamps were left in the handles projecting through the incision, which was closed in the usual manner.

Postoperative History.—The patient was on the operating table forty-five minutes, and when removed to bed the temperature was 99.6, the pulse 128, and the respirations 28. There was no sign of shock.

The clamps that were left in the wound for forepressure

were removed on the fifth, the gauze on the sixth, and the stitches on the ninth day after operation.

The patient had an uneventful recovery, with the exception of a mild delirium on the fourth, fifth and sixth days after operation, and was discharged, cured and in excellent condition, on May 2, 1905, forty-five days after operation.

Of interest in determining the permeability of the left kidney after operation by gauging its intensity of elimination is the appended urinary table for the two weeks following operation:

POSTOPERATIVE URINARY FINDINGS.

Date.	Amount in 24 hrs., c.c.	Sp. Gr.	Color.	Albumin.	Urea, per cent.	Microscopic Findings.
Mar. 17	1629	1.029	Dark brown...	Trace...	1.2	Numerous red blood cells.
" 18	700	1032	Reddish brown...	Trace...	1.2	No tubercle bacilli.
" 19	1110	1025	Yellow...	Absent...	1.2	Phosphates, urates.
" 20	950	1028	Amber...	Faint trace.	1.2	Phosphates, uric acid.
" 21	875	1028	Yellow...	Very faint trace.	1.2	Phosphates, urates.
" 22	630	1034	Reddish yellow.	Absent...	1.2	" "
" 23	829	1032	Cloudy yellow.	Trace...	1.2	" "

April 1	700	1021	Yellow...	Faint trace.	1.9	" "

* Plus.

N. B.—Glucose always absent. Reaction invariably acid.

Examination of Kidney.—The kidney was examined by Dr. A. O. J. Kelly, who kindly furnished the following report:

The kidney, when removed, was fragmented and partly disorganized, and measured 11x6x4 cm. The lower two-thirds were surrounded by, and lay flattened against, the sac of a false aneurism. The kidney tissue in this region consisted almost exclusively of cortex, and varied in thickness from 4 to 8 mm., but was very much attenuated at the extreme lower pole, where rupture had occurred. The tissue was much compressed, and immediately adjacent to the blood clot it was quite fibroid. The cortex of the kidney elsewhere than immediately surrounding the false aneurism contained a few small cysts. The renal artery, having been cut off close to the kidney, could not be further studied.

Microscopically, areas of chronic parenchymatous nephritis, with moderate fibrosis and round-cell infiltration, were found.

By consulting the literature, I find that in all twenty-two cases of aneurism of the renal arteries have been detailed by other writers. Keen¹ described a nephrectomy for a large aneurism of the right renal artery, and gave a résumé of twelve previously reported cases of renal aneurism.

Morris² described a case of aneurism of the left renal artery, and gave abstracts of twenty-one previously reported cases.

P. Ziegler³ gave a general résumé of the subject of renal aneurisms, together with abstracts of twenty cases which he had collected.

Through the kindness of the librarian in the surgeon-general's office, Major-Surgeon Walter H. McCan, I have collected four more cases, and these, together with the case here reported, bring the recorded cases up to twenty-seven. This is the fifth patient who has been operated on; of the other four, one died.

Ziegler³ has described the etiology, symptomatology, diagnosis, prognosis and treatment of renal aneurisms.

1. Keen: Philadelphia Med. Jour., 1900, vol. v, p. 1038.

2. Morris: Lancet, 1900, vol. II, p. 1002.

3. Ziegler: Centralbl. f. d. Grenzgeb. d. Med. u. Chir., Jena, 1903, vol. VI, pp. 2-8.

so well that I would deem this article incomplete should I not quote him:

"Of aneurisms, those of the renal arteries are among the rarest, and . . . are rarer than splenic aneurisms. Their aneurism is small, it may possibly give no symptoms and perhaps will only be relieved accidentally during the course of an operation. Later it may produce a tumor and bring about atrophy of the kidney, finally rupturing into the renal space, accompanied by severe hemorrhage, causing death, or not progressing so rapidly, a sac is formed at the false aneurism, in which repeated small hemorrhages lodge.

"The bleeding can become fatal before a tumor has made its appearance. . . . Sooner or later a tumor will always form, and this is, besides the hemorrhage, the most serious symptom. The tumor may give rise to no pain or may be accompanied by most excruciating pains; the size of the tumor may vary from that of a fist to a man's head. . . . Pulsation is absent in renal aneurisms, since the artery is too small in proportion to the size of the sac for the impulse of the blood to be great enough to expand the sac sufficiently that it may be made manifest; so, too, auscultation rarely gives results. The ordinary symptoms that arise from the escape of blood or from the pressure of the tumor are very unreliable; mistakes are very readily made with neoplasms, hydronephrosis and hemato-nephrosis. In neoplasms, rapid growth, followed by emaciation and mild bleeding, are characteristic, and, in the presence of metastases, the diagnosis is clearer. In hydronephrosis, which also can be of traumatic origin, bleeding is seldom met with.

"The prognosis is extremely unfavorable. All cases in which no operation was done terminated fatally, and of these the cause of death was hemorrhage into the renal space, venter or retroperitoneal space.

"As to treatment, nephrectomy alone is to be considered, and, by all means, the transperitoneal method is to be preferred on account of the ease with which the renal vessels may be quickly ligated."

Ziegler then gives abstracts of twenty cases which had been reported up to January, 1903.

I have collected the following four cases:

1. Fulton¹ writes of a woman, aged 36, with a history of severe pain in the right side with more or less collapse a day or two before admission to the Rhode Island Hospital. The diagnosis of extrauterine pregnancy was considered the most probable one, but the patient was not operated on because of her extreme condition, and she died shortly afterward. There was found at autopsy an enormous hemorrhage, retroperitoneally, on the right side, extending from the diaphragm to the brim of the pelvis. The kidney lay in the midst of this mass of blood clot. About one inch from the origin of the renal artery, there was an aneurismal dilatation of that vessel; this had ruptured, causing the hemorrhage.

2. Abbott² reports on a specimen showing a small sacular aneurism on an accessory branch of the right renal artery. The history, in brief, is that of a woman, aged 56, who two years previously fell heavily, injuring her back, and who had never felt well since. Eighteen months later the patient sustained another heavy fall. A year ago she began to suffer from the renal insufficiency, which caused her death. Postmortem examination revealed a general anasarca and advanced chronic interstitial nephritis. The renal arteries were distinctly calcareous; the other arteries showed beginning atheroma. The right kidney showed four cicatrices, and, microscopically, advanced chronic interstitial nephritis, with marked periglomerulitis and atrophy of the tubules. In the medulla were hemorrhagic areas.

Of interest in this case is the association of three possible causative factors: a heavy fall, in which the patient injured her back; a chronic interstitial nephri-

tis, and marked calcareous degeneration of the renal arteries. The specimen, described by Abbott, shows a small aneurism on an accessory branch of the right renal artery, just beyond its origin, which presents a small excrescence, the size of a marrow-fat pea, on the posterior surface of the vessel. The contents of the sac were a single free, homogeneous blood clot. At the proximal end of the sac there was beginning fatty degeneration. There were no symptoms of aneurism of the renal artery present.

3. Barnard³ reports a very interesting case of a small calcified and cured aneurism of the right renal artery that caused the death of the patient in a peculiar manner. A boy, aged 9, was thrown from a runaway horse, falling heavily to the ground on his back and right side. On account of signs of hemorrhage into the venter, he was operated on the next day, and about 750 c.c. of black fluid blood were removed from the peritoneum, and a rent in the right lobe of the liver was found and packed. Death occurred the following day.

The postmortem examination revealed an aneurism, the size of a hazel nut on the upper of two branches of the right renal artery, the contents of which had partially calcified and had thus brought about a cure. The heart revealed a stenosis of the mitral valve, an embolus from which probably caused the aneurism.

Of further interest in this case are the facts not only that the aneurism and renal artery escaped uninjured, but also that the aneurism conducted the violence from the loin to the duodenum and liver, bruising the duodenum, and causing a stellate fracture of the liver that radiated from the renal impression, and a wedge-shaped area of pulping of the hepatic tissue, the apex of the wedge corresponding with the calcified aneurism. The base of the wedge appeared on the surface of the liver and allowed the free escape of blood into the peritoneum.

The kidney itself had escaped injury, but between the true and the fatty capsule of the right kidney, on its posterior surface, was a considerable hematoma, and this extended around the posterior surface of the aneurism.

4. Barnard⁴ cites the case of a little girl, whom he examined. The child was dying of malignant endocarditis and developed suddenly a large, diffuse swelling in the left loin behind the colon. At necropsy, this was shown to be a large collection of blood which had escaped from a ruptured aneurism of the left renal artery.

I emphasize Morris⁵ valuable warning that as soon as the nature of the tumor is ascertained, the renal pedicle should be reached, and the renal artery ligated before attempting to empty or to remove the sac. The wisdom of this dictum is self-evident. The text-books do not mention aneurisms of the renal arteries, an error of omission that, I believe, should be corrected.

In cases in which a fall from a height with evidences of resultant injury to a kidney has occurred, and in which there is hemorrhage, it would be well to consider the diagnosis of aneurism of the renal artery, which is a diagnosis more definite than that of essential kidney hemorrhage.

In closing, I call attention to the fact, more of interest than of practical importance, that of all the arteries of the body the renal, when the site of a symptom-producing aneurism not involving the abdominal aorta, is one of the few that offers an ideal cure—total extirpation of the artery (and kidney) without interfering with the blood supply of any other part of the body.

SUPERSTITIONS IN MEDICINE.

Superstition is a rather illusive word to define, and yet if we go back to its etymologic derivation from the Latin it is not difficult to understand. It comes from the Latin word *superstes*—a survivor. Superstitions then are survivals from a previous set of beliefs or opinions in any department of thinking which still continue to have their influence over men's actions though they have lost their basis or supposed basis in truth because of the evolution of the department of thought in which they occur. In the old days when many phenomena that are now readily explicable on natural grounds were incapable of explanation, theories were invented, such as those of ghosts and witches, and these were supposed to afford the desired reasons for things which the human mind is always so prone to seek. Most of these beliefs have disappeared in the progress of modern science and of education, yet there are some people who still continue to be ruled or at least influenced by the survival of the old theories, that is, by superstitions.

It is almost needless to say that there are not a few superstitions left in medicine; we mean even in scientific medicine. Popular medicine is full to overflowing with them. There are plenty of reasonably intelligent people, including many lawyers and ministers of the Gospel, in this country who still wear plain iron rings on their fingers, confident that somehow the electricity which they have been told flows from this into their systems prevents the occurrence of rheumatic and nervous pains of many kinds. Faithfully every second or third day they rub out the interior of the ring when it has become rusted because of perspiration and congratulate themselves on the fact that they are wearing it because here is the actual evidence on the inside of the ring that it is drawing various forms of insalutary material out of their systems.

This principle that something can be put on the outside of the body which will draw out evils from within has never lost its hold on the popular imagination, and indeed there are many physicians who apparently still cling to it. The poultice is still used by a great many practitioners of medicine with at least the subconscious idea that it will help to bring noxious material to the surface. A poultice, according to our modern medical scientific principles, is nothing more than a method of applying moist heat to the body. It does not matter then in the slightest degree what the poultice is com-

posed of, provided only that it is able to retain heat and moisture well for a reasonable period. There are many who still consider that the selection of the material of which the poultice shall be made for various diseases is extremely important. A linseed meal poultice is used in pneumonia, an Indian meal poultice is preferred in peritonitis, while there are some who consider that for erysipelas and for red and swollen joints a cranberry poultice is more effective than any other. These opinions are, of course, medical superstitions, survivals of the time when the drawing power of the poultice was considered to be its main reason for use.

There are superstitions, however, in departments of medicine that have been much more successfully studied. Notwithstanding the fact that it is now generally recognized that typhoid fever is a generalized infectious disease with a local manifestation, usually though by no means always or necessarily in the intestine, there are still many who believe that the medication for typhoid fever should always be directed to the administration of antiseptics which will hamper the growth of the typhoid bacilli in the intestinal ulcers. Even if these were killed there are always other typhoid bacilli in the system and the disease will run its course. Besides it seems to be forgotten that bacteria of all kinds are cellular organisms and that the body is composed of cells. Bacteria have learned to live alone and are hardy cells. The cells of the body, with their habit of dependence and living in colonies, are much less vital. As a consequence it would seem to be almost a certainty that any substance which would kill bacteria within the body would work serious ravages among all the body cells with which it came in contact. Of course it is possible that some substance might be obtained with a specific action against the bacteria and harmless for body cells. Such has actually been found for the micro-organism which causes malaria, but that is the only case on record, and the search for specifics has been one of the most unsatisfactory departments of investigation in medicine.

It is generally acknowledged at the present moment that acute articular rheumatism is due to a specific micro-organism, though it is not yet definitely decided just what that micro-organism is. In spite of the consensus of opinion in this matter, however, medical discussions still continue to be liberally interlarded with the most curious survivals of the older theory of the metabolic origin of rheumatism, superstitions for which there is no longer any basis in medical theory or knowledge. Physicians still talk of the rheumatic diathesis just as if there was a definite tendency to the occurrence of this disease somehow engendered in the tissues before infection. It is true that rheumatism once suffered from is likely to recur, but the same is true of pneumonia. We do not for that reason talk of a pneumonia diathesis. The question of heredity in rheumatism is still considered important by many, though how there can be heredity that affects the taking of an acute infectious disease is hard to understand.

In the minds of many physicians this same question of heredity still maintains much of the importance that it was formerly supposed to hold in pulmonary tuberculosis, though now the infectious nature of the disease, and even its contagiousness, is universally recognized. In the old days, at the beginning of the nineteenth century, before the various infectious fevers of childhood were separated from one another and clearly defined, morbid constitutional tendencies to these diseases were supposed to exist and hereditary elements were supposed to enter into the causation of them. These older superstitions have disappeared, but we have more modern survivals of antiquated theories to take their place. Apparently it would be well occasionally to make a review of the opinions we hold, in order to see how many of them are based on up-to-date knowledge and how many are hold-overs from a previous state of knowledge no longer justified by present medical conditions and progress.

METASTASIS OF BENIGN TUMORS.

At the annual meeting of the German Pathologic Society at Kassel in 1903 Bormmann of Göttingen reported a most interesting case of atypical tumor formation. It concerned a young woman who had suffered for three years from a hard, dark-red tumor, which recurred repeatedly after its removal, in all six times. Death resulted from extensive metastases in the lungs, in addition to which a nodule was found in the gluteal region, as well as existing recurrences in the scar. The remarkable feature of the tumor was, however, that in spite of this extensive metastasis and persistent recurrence in the primary site, the histologic structure was that of a typical benign growth. Bormmann could find not the slightest feature of malignancy in the growth, and characterized it as a simple hemangioma. All the recurrent growths and metastases presented the same appearances of masses of new-formed blood vessels, composed of mature cells, with perfect endothelial linings, which were often proliferated into the lumen of large vessels in a papilloma-like formation.

This case brings up a question of great interest and importance to the surgeon as well as to the pathologist—can benign tumors produce metastases? There occur in the literature a number of instances in which apparently typical chondromas, chiefly the large irregular growths of the pelvic bones, have grown into blood vessels and produced secondary growths in remote places, particularly in the lungs. These tumors have been structurally the same as the ordinary benign chondromas. Besides the chondromas the chief instances of apparent metastases of benign tumors have arisen from what appeared to be benign tumors of the thyroid. There are now in the literature reports of some twenty or more cases of this kind. These metastases have been found particularly in the bones, and as a rule the bone tumor has been removed at operation under the natural assumption that it was the primary growth. Not in-

frequently the secondary growths have been multiple, and occasionally the viscera, particularly the lungs, have been involved. The thyroid in these cases has shown either a simple diffuse goiter, or, more commonly, a small nodule of apparently benign adenomatous tissue; in any event, there has never been any growth in the thyroid that would even be considered as malignant, either from its gross or microscopic appearances, were it not for the suspicious coexistence of metastases. The secondary growths also have usually reproduced either the structure of simple adenoma or of typical normal thyroid tissue, so that some have been reported as instances of metastasis of normal thyroid tissue without a primary tumor. Beyond these two forms of growths there are practically no instances known of metastasis of non-malignant tissue; a few examples of secondary growths from benign gliomas, myomas and liver adenomas have been described, but they are for the most part doubtful.

We may interpret these observations in either of two ways. With v. Hansemann we may consider that the mere fact that metastasis has occurred is proof positive of the malignancy of a growth and characterize them, as Orth did Bormmann's case, as "metastasis formation by an otherwise benign tumor." In support of this is the fact that a number of these cases have resulted fatally from the effects of the secondary growths, as happened with the classical case of Oderfeld and Steinhaus.¹ On the other hand, we must consider the suggestive fact that the chief examples of the condition under consideration occur from tissues whose capacity for transplantation is perhaps greater than that of any other tissues in the body. If pieces of normal cartilage are implanted into animals, even of a foreign species, they will remain alive for a great length of time, and if injected into vessels they may live and grow slightly in the organs in which they lodge. When very young embryos have been injected or implanted into animals for the purpose of studying tumor theories, it has been found that the cartilage is the chief tissue that survives and practically the only one that grows. Likewise, of all the parenchymatous organs, the thyroid shows the greatest vitality when transplanted. Even the law of specificity of cells seems to fail here, for sheep thyroids have been successfully implanted into the human body, maintaining their vitality for some time. It seems to us that these facts are more than mere coincidences, and that it is quite possible that fragments of thyroid tissue or of chondroma tissue, when dislodged and taken into the blood vessels in the form of cells from a benign tumor, might continue to grow where they lodged, producing a true metastasis, without any other feature of malignancy. Such a growth could be properly designated only as a metastasis of benign tissue, and should be considered as an exception to the otherwise invariable rule that "metastasis means malignancy."

THE PUBLIC HEALTH SERVICE AS A CAREER.

Dr. Westbrook's interesting presidential address before the American Public Health Association¹ brings up once more a question which every intelligent physician should ask himself in all seriousness and contriteness of spirit: What can be done by the medical profession to strengthen the quality of public health work? Amelioration and palliation may take many forms, but the real problem often narrows down to a consideration of ways and means of obtaining trained and efficient service.

In Great Britain, as is known, a diploma in Public Health is required of candidates for the position of health officer. For this diploma special regulations have been laid down by the general medical council of Great Britain, which are designed to insure "a position of distinctly high proficiency, scientific and practical, in all the branches of study which concern public health." In other words, special qualification, involving both laboratory training and outdoor sanitary work, are demanded of those who wish to enter this important field.

The sanitary organization and administration of many German, French and English cities in certain features are so far in advance of much current American practice as to make the latter seem bungling and wasteful by comparison. It is not that improvement has not been made. The pessimistically inclined should be referred for encouragement to the condition of the New York Health Department in 1864 as set forth in Andrew D. White's recently published autobiography. The "health officers" and "health inspectors" of forty years ago were men who owned great blocks of tenement houses, in which they "kept low drinking bars." While a unit in ignorance and neglect of their duty, they were shown in the course of a legislative inquiry to be at variance in respect to the importance of "highjinnicks" (hygienics), a term that was introduced as meaning "persons who doctor themselves," and afterward interpreted by others as "bad smells that arise from standing water," or more commonly as a disease that was "quite serious" or "pretty bad" in the inspector's district, although one witness thought there was "not much of it." It is at least a satisfaction to believe that the return of Boole and his assistant inspectors is as remote as the return of the dodo.

At the same time, it is hardly to the point to urge that things have been or might be worse; our contention should be that they can easily be better. Are the best-educated and most influential men in the medical profession really throwing all their weight in support of modern and enlightened sanitary organization, or are they inclined to regard interest in municipal health affairs as unwise and as trenching on "politics" - to use a good word that Americans have helped to bring into disrepute? There are in this country hundreds of devoted and capable men engaged in the work

of safeguarding the public health who must feel at times isolated and apart from the great body of the medical profession. We should ask ourselves if this could be the case if the profession presented a united front to the onslaughts of all the varied interests that stand for revenue only in the modern city. There can be no question as to the impression that would be made on the community if the leading physicians stood solidly together and showed an active interest in developing and sustaining an efficient system of municipal hygiene. We have lately seen the speedy "volte-face" executed by an incredulous and jeering press as a result of the support given by physicians to the doctrine of mosquito transmission of yellow fever.

It is partly, possibly largely, because public health work has been regarded sometimes as an avocation that any physician can "pick up," and sometimes as an occupation only remotely concerning the practicing physician, that it has not yet afforded the opportunities for a career that are offered by other specialties. Native aptitude and proper training are essential to a successful career in the public health service; so are the appreciation and co-operation of those members of the community whose attainments best fit them to judge of the methods and fruits of the work of health officials.

OBLITERATING ENDOPHLEBITIS OF THE HEPATIC VEINS.

Some five or six years ago Chiari, of Prague, at a meeting of the German Pathological Society, called attention to a condition which clinically resembles cirrhosis of the liver, but which is due to an obliterating endophlebitis of the hepatic veins. The lesion had been described as early as 1846 by Budd in his well-known work on diseases of the liver, but, like many other rare conditions, it had been almost forgotten till Chiari again called attention to it. In the routine autopsy technic as usually practiced, the condition of the orifices of the hepatic veins, as a rule, is not investigated, and the experience of Chiari, who has observed seven cases of this condition in a few years, suggests that a great many must have been overlooked, probably because there is a definite cirrhosis of the liver in most cases, and this has been taken for the primary lesion.

The reported cases of obliterating endophlebitis of the hepatic veins have been recently collected by Hess,¹ who has made a careful study of them. So far not a single case has been recognized in the United States, though such cases must have occurred from time to time. The clinical picture of the disease resembles very closely that of ordinary cirrhosis of the liver. Males and females are about equally affected, and, in contradistinction to ordinary cirrhosis, the disease usually occurs in young adults. The onset of the symptoms is gradual, and most cases run a chronic course, though in rare cases the disease lasts only a few weeks. The first symptom is

¹ THE JOURNAL, Dec. 16, 1905.

¹ Amer. Jour. Med. Sci., 1905, Vol. cxxx, p. 986.

often abdominal pain, and this may be severe, but is more usually mild, at any rate at first. In some cases the swelling of the abdomen is the first symptom which calls attention to the condition. Gastric symptoms may be prominent, as in cirrhosis, but in many of the recorded cases they are not noted. Ascites, distended abdominal veins, and enlarged spleen are fairly constant. Edema is a late symptom, and slight jaundice is not infrequently noted. The liver is usually enlarged, so that the cases resemble hypertrophic rather than atrophic cirrhosis. The usual length of time between the appearance of symptoms and death is about six months. In very rare instances, as in the case reported by Leichtenstern, death occurred in less than two weeks, with very acute gastrointestinal symptoms.

The etiology of this affection is obscure, and almost every one who has recorded cases has a different explanation. Chiari suggested a syphilitic inflammation of the veins, but on rather slender grounds, at any rate in some cases. In many of the other reported cases there is no suspicion of syphilis, and it seems quite certain that this disease can not be an invariable factor. Other causes mentioned are trauma, congenital malformation, perihepatitis, hepatitis, and thrombosis.

The differential diagnosis between this condition and ordinary cirrhosis must be very difficult, if not in many cases impossible. According to Hess, a positive diagnosis has never been made *intra vitam*. When we consider that the effect of damming back of the blood in the hepatic veins is, in the end, the same as that of portal obstruction, this is not to be wondered at. The condition, however, is one that should be thought of more frequently than it is at present. In a case resembling ordinary cirrhosis, but occurring in a young individual in whom the ordinary causes of cirrhosis are lacking, we should certainly be suspicious. The occurrence of pain over the hepatic area, which is rare in cirrhosis, should also make us hesitate before making the latter diagnosis. The rapidity of onset of the ascites and the rapid reaccumulation of ascitic fluid after tapping are suggestive of complete obstruction rather than the partial obstruction of cirrhosis, though not by any means pathognomonic. Taking all these points into consideration, it seems certain that from time to time we shall meet with cases in which we must seriously suspect endophlebitis of the hepatic veins, even if we can not positively diagnose it. It seems probable that the condition will become much more common as it becomes more widely known.

THE DEATH ROLL OF 1905.

In the Necrology Department of THE JOURNAL 2,015 deaths of physicians in the United States and Canada were recorded during 1905. On an estimated medical population of 125,000, the death rate for the year is 16.36 per 1,000—no material change from previous years, as in 1902 the estimated mortality rate per 1,000

was 14.74; in 1903, 13.73, and in 1904, 17.14. The age at death varied from 23 to 104 years, the average being 61; the number of years of practice varied from 0 to 75, the average length being 31 years and 1 month. Below we go more into detail on these and other points for the benefit of those interested.

The chief difficulty still met with is the incompleteness of the obtainable data regarding deaths. In the death notices of the year, no explicit cause of death was given in 706 instances, or 34.52 per cent.; the number of years of practice was omitted in 105 cases, or 5.14 per cent., and no information regarding age was obtainable in 284 cases, or 13.88 per cent., and this in spite of correspondence in hundreds of cases.

Of the decedents, 167 were members of the American Medical Association, and of these 7 had held official positions in the organization; 170 were chronicled as being members of the various state medical societies; 35 as members of district societies; 175 as members of county societies; 32 as members of local societies; 5 had been delegates to the international medical congresses, and 2 were members of the British Medical Association.

The military records for the dead of last year disclose the fact that 184 had served their country for the north and 70 for the south in the Civil War; 11 were veterans of the Mexican War; 2 had seen service in Indian campaigns; 12 in the Spanish-American War, and 10 had participated in foreign wars. Of present and past officers of the Medical Department of the Army, 35 died during the year; of naval officers, 21, and 2 officers of the U. S. P. H. & M.-H. Service. The national guard lost 16 medical officers, 3 of whom had attained the rank of surgeon-general, and 2 that of assistant surgeon-general.

Among civil positions of honor held by the dead here noted were the following: Congressmen, 3; state senators, 15; members of legislature, 53; U. S. consuls, 3; judges and court officials, 15; mayors, 34; councilmen, 22; postmasters, 12; county treasurers, 7; coroners, 33, and revenue collectors, 7.

Many of the deceased were prominent in educational matters: 4 had served as members of boards of regents of state universities; 22 as superintendents of schools or members of school boards; 64 as professors, lecturers or instructors in medical colleges, and 28 as members of state boards of health and medical examination and registration.

Among the medical positions held were 101 as health officers or members of health boards, 22 as county physicians, and 26 as superintendents of state or general hospitals. Nine of the deceased were editors of medical journals.

As before, "heart disease" heads the list of deaths causes. To this are assigned 202 deaths, 15 of which were from angina pectoris, 4 from endocarditis and 2 from myocarditis. Cerebral hemorrhage, which includes most of the deaths ascribed to "paralysis" and

"apoplexy," caused 153 deaths; pneumonia, 111; tuberculosis, 102, of which 4 were peritoneal, 2 laryngeal, 2 of bones, 1 renal, and 1 intestinal; nephritis, including Bright's disease and dropsy, 100; senile debility, 80; accidents, 72, of which 11 were due to morphin poisoning, 10 to drowning, 9 to railway accidents, 7 to falls, 5 to fractures of hip in the aged, 4 each to gunshot wounds and street railway casualties, and 3 each to burns, carbolic acid poisoning and runaways (poison alone caused 19 of the 72 deaths); after surgical operations, 53; suicide, 46, including 26 by gunshot wounds, 7 by morphin, 4 by carbolic acid, 4 by exsanguination, and 3 by strangulation; typhoid fever, 41; malignant disease, 34; septicemia, 28; appendicitis, 27; paralysis, 25; influenza, 21; uremia, 122; homicide, 20, including 13 by gunshot wounds, of whom 1 was killed while resisting an officer, 4 were killed in duels and 1 medical officer was killed in battle in the Philippines; meningitis, 16; liver diseases, 15; diabetes, 13; gastritis, 10; peritonitis, paresis and gall-bladder disease, each, 8; locomotor ataxia and hemorrhage of the lungs, each, 7; malaria, intestinal disease and insanity, each, 6; yellow fever, neurasthenia, erysipelas, brain disease and alcoholism, each, 5; pernicious anemia, 4; and, hematemesia, scarlet fever, smallpox, exposure, and diphtheria, each, 3. Of the total deaths, 138 were chargeable to violence; 72 were due to accident, 21 less than in 1904, 1 more than in 1903, and 12 more than in 1902; 46 were due to suicide, 10 more than in 1904, 22 more than in 1903, 23 more than in 1902; and 20 were due to homicide, 8 more than in 1904, 10 more than in 1903, and 7 more than in 1902.

The ages of the deceased varied between 23 and 104 years. Below the age of 30, 62 died; above the age of 70, 103; above the age of 80, 239; beyond 90, 23, and 2 had passed the century mark.

The extreme limits of years of practice varied between the year of graduation and 75 years. Eleven died in their year of graduation; 6 had been in practice more than 70 years; 65 more than 60 years; 303 more than 50 years; 629 more than 40 years; 982 more than 30 years; 1,467 more than 20 years, and 1,806 more than 10 years.

Among the notable dead of the year are the following:

Dr. Byron Cook Pennington, Atlantic City, N. J., fourth vice-president of the American Medical Association and chairman of general committee of arrangements for the 1901 session.

Dr. Albert B. Prescott, Ann Arbor, Mich., eminent as a chemist, author and teacher.

Dr. Walter S. Christopher, Chicago, eminent as a specialist on diseases of children, a pioneer for child study and medical inspection of schools.

Dr. Ernest J. Mellish, El Paso, Texas, prominent anæsthetist.

Dr. Charles Stuart, assistant surgeon-general U. S. Army, eminent as a chemist, a recognized authority on military hygiene and sanitation.

Dr. Henry Putnam Stearns, Hartford, Conn., teacher, alienist and expert on insanity.

Dr. Augustus Palmer Dudley, New York City, gynecologist, teacher and writer.

Dr. James Read Chadwick, Boston, obstetrician and gynecologist.

Dr. John Arvid Ouchterlony, Louisville, Ky., practitioner, teacher and writer.

Dr. Henry Darwin Didama, Syracuse, N. Y., vice-president of the American Medical Association in 1875, dean of Syracuse University College of Medicine.

Dr. Robert Henry Harrison, Columbus, Texas, vice-president of the American Medical Association in 1875, expert on yellow fever.

Dr. James Montgomery Holloway, Louisville, Ky., eminent teacher and practitioner.

Dr. Daniel E. Nelson, Chattanooga, member of House of Delegates of the American Medical Association.

Dr. Ambrose Loomis Ranney, New York City, anatomist and teacher.

Dr. William S. Forbes, Philadelphia, teacher of anatomy and author of original Anatomy Act.

POSTAL CHECK SYSTEM.

A bill has been introduced into both houses of Congress which provides for the printing of one-dollar, two-dollar and five-dollar bills with a blank space for a name. Such a bill could be used as currency until this space is filled in, after which it would be payable only to the individual indicated. In other words, when an individual desires to send one, two or five dollars through the mail he can do so with a postal check with the same safety as with his own check by filling in the name of the individual to whom he wishes it paid. When the payee receives the check he endorses it as he would similar paper, presents it at the nearest postoffice and it is cashed. The only expense to this transaction is two cents for a stamp to be placed on the bill. Certainly if there is anything that the government should provide for the public it is a more simple method of transferring small amounts of money than now prevails. At the present time one has to go to a postoffice, express office or bank for the accommodations these several institutions furnish or send his personal check. In either of the three former cases it costs him time and money; in the latter case it also costs him, or the one to whom the check is sent, more money than by either of the other methods unless he lives in one of the very few large cities, such as Chicago or New York. Recently the clearing house of the Chicago banks has adopted stringent rules by which the banks receive at least ten cents on every check that is cashed by them from out of town, except a few of the very large cities, and more if the amount of the check exceeds \$10.00. The adoption by the government of the postal check system would be against the interests of the express companies and the banks, and consequently these two big interests have opposed it. Who will represent the public before Congress? This matter is not of interest to physicians, except that it is of interest to every man who desires to

transfer money from one place to another. THE JOURNAL is particularly interested because it receives thousands of small checks during the year, and the ruling of the banks means an enormous added expense which either THE JOURNAL or the individual sending the check must pay. It is hoped that public sentiment will be so aroused in favor of this advantageous manner of transferring money that Congress will be compelled to adopt the postal check system, in spite of the opposition of the banks and express companies.

THE UNITED PROFESSION IN THE EMPIRE STATE.

In last week's issue of THE JOURNAL, under the head of Association News, appeared letters from the President and the General Secretary of the American Medical Association to the corresponding officers of the reorganized Medical Society of the State of New York relating to the perfected union of the two state medical organizations in the Empire State. That all difficulties in the way of such an union have been overcome, that all legal technicalities have been fulfilled, and that the amalgamation, so long desired, has been accomplished with practical unanimity and in the most admirable spirit, will afford sincere gratification to the entire profession. The congratulatory sentiments expressed by the general officers of the American Medical Association voice the feeling of the entire medical profession of America. With the largest number of physicians of any state of the Union, and with the superb personnel of the profession of New York City and of the entire state, the reorganized society has opportunities such as have come to no other state society. With wise and prudent leadership, and with absolute obliteration of every remnant of past disagreement, the reorganized society will enter a new era of achievement which will surpass all previous accomplishments and which will be worthy of its noble traditions. By affiliation with the American Medical Association its work and influence will be unlimited and will assume the highest importance in the national organization of the profession. The nearly fifty thousand members of the organized profession in America heartily rejoice with their brethren of the state of New York that the union and concord long anticipated have now become realities.

ANOTHER FRAUD CHECKED.

The postoffice department, with the co-operation of the Bureau of Chemistry of the Department of Agriculture, is doing most effective work, in a quiet way, in protecting the public from medical frauds. Of course, this work is not far reaching, for it is limited to those frauds that depend, more or less at least, on the postoffice for their success. We have published accounts of several fraud orders issued by the department, and this week we give space to another. A campaign has been conducted for the postoffice department by the Bureau of Chemistry against "manhood restorers," those which are in the form of medicines, but there have sprung up a number of firms which exploit mechanical contrivances—"developers." These affairs are not only means of swindling the ignorant and deluded out of their money, but they are

positively harmful, and with them it is absolutely impossible to accomplish any good. We understand that several other firms handling such contrivances are now under investigation. It is certainly encouraging that there is one branch of the government attempting to check the vultures who are preying on the fears of our youth, and this good work is going on and few know of it—none practically except those directly interested. For some reason the newspapers make no mention of these fraud orders when they apply to medicines, but do so when they relate to commercial affairs.

IS THERE CONCUSSION OF NERVES?

Concussion is a term which found early use in medicine to define a condition produced by violence and described as a "jarring" or "molecular disturbance" of an organ or part without gross or perceptible lesions and accompanied by a more or less complete but temporary suspension of function. For a time the term was applied to almost any organ, but following the increase in our knowledge of actual lesions its use gradually became restricted until at the present time it is seldom used except in connection with injuries involving some part of the nervous system, and even in this connection its applicability to the spinal cord has been strenuously contested by many writers. Archibald Young of London, in a recent article on "Gunshot Wounds of Peripheral Nerves," declares there is no such thing as concussion of a nerve. This opinion is based on his studies in a number of cases of injuries involving the peripheral nerves during the Boer War in South Africa. Most of these injuries were produced by bullets of various sizes and were just such as theoretically would most likely give rise to the symptoms of so-called concussion in the parts involved or in those immediately adjacent thereto. The occurrence of cases in which a single nerve trunk or cord is picked out from the midst of a closely-related "complex" with the absence of any signs of concussion of the remaining cords of that "complex" on the one hand, and on the other hand cases in which all the constituents save one trunk of a nerve "complex" are involved, would seem to indicate that the symptoms when present must be due to a distinctive injury to the nerve. That the symptoms in some cases may be transitory is clearly shown, but in these cases it is contended that there is always a contusion with swelling, edema, or ecchymosis of varying degree present. As a result of his studies Young concludes that "it is useless, if not, indeed, actually unsound, to adopt any special 'concussion' class of nerve implication associated with gunshot wounds." While it is perhaps possible to conceive of a "molecular disturbance" affecting a mass of cells such as are found in the brain, and which are constantly active, transforming or giving out energy, it becomes an entirely different matter when it concerns a structure which is purely passive in its function, such as a nerve cord, and we thus find the term "concussion" still further restricted in its applicability.

MEDICAL SPEAKERS AT ANTISCIENTIFIC MEETINGS.

One of the measures advocated by the new Austrian antiquackery society¹ is that of having bright and able medical men attend meetings of antivivisectionists and other faddists, in order to reply on the spot to statements discrediting science and scientific methods of research. A good example of the power of such work is given in a recent issue of the *British Medical Journal*. Richardson Cross rose and made a telling reply to Stephen Coleridge, an ardent antivivisectionist. Among other things, Mr. Cross asked if the persons present would admit, if it were possible or probable that some useful knowledge of the terrible disease, cancer, might be obtained from investigations under anesthetics of a limited number of animals, that it would not be justifiable. He was cheered frequently and was included in the vote of thanks tendered the speakers. Our British contemporary concludes its description of the meeting with the remark: "It is an unpleasant task to contend against prejudice and stupidity, but if medical men would come forward oftener in defense of scientific progress the itinerant propagandists would be more careful in their statements. As the whole strength of their crusade lies in exaggeration, which is too often left uncontradicted, it would crumble away before the power of the plain truth."

THE IMMIGRATION QUESTION.

During the year ending June 30, 1905, according to official figures, over one million emigrants landed in this country, thus eclipsing all previous records. With such an influx it would seem impossible that all could be of a desirable class, and the question was discussed at some length at the National Conference on Immigration, which recently met in New York. This body, composed of delegates from every portion of the United States and fairly representative of public opinion on this subject, adopted certain resolutions, including recommendation of changes in the present law regulating immigration and the stricter enforcement of existing regulations. Among the changes suggested were the extension of definitions of the excluded classes, defining the term "likely to become public charities" so as to include "all persons of enfeebled vitality, whether such condition is due to defect, inheritance, disease or to advanced age," and advocating the examination of intending immigrants at their homes or at points of embarkation, the requirement from each immigrant of a certified document containing a careful description of the person to whom it is issued similar to a passport, and also the increase of penalties on steamship companies for transporting undesirable immigrants. It is a well-known fact that certain European governments have made a practice of unloading some of their undesirable citizens on this country, and that transportation companies have not been scrupulous in increasing their profits on immigrants. The matter has become of such importance that President Roosevelt, in his recent message, emphatically called attention to these facts and suggested rem-

edies. The matter is one of the questions of present importance for our country. Leaving aside the purely economic and sociologic considerations and taking up only those of medical interest, there is still a good deal to be said on the subject. Besides those actually suffering from physical disease, there is a vast number among the foreigners who land on our shores who are mentally unfitted for the stress of life and conditions they will inevitably meet with here. The result is physical or mental breakdown and the overburdening of our public and private charities, to say nothing of the general deterioration which such an element of the population is liable to induce. The question of urban congestion is also a serious one with many medical aspects, and it is largely contributed to by foreign immigration. The bulk of immigrants nowadays, it is said, do not go into the country as agricultural laborers, but settle down in the cities among those of their own race. The medical profession has the opportunity more than almost any other class of men of studying many of the problems that are involved and of pointing out the way to their solution. It is a matter of public duty which it should not neglect.

Medical News

CALIFORNIA.

New Laboratory at Presidio.—The new laboratory for the United States Army General Hospital at the Presidio of San Francisco, erected at a cost of \$12,000, is now completed and ready for occupancy.

County Society Meets.—The Los Angeles County Medical Society held its annual meeting December 15, at which Dr. Fitch C. E. Mattison, Pasadena, was elected president, and Dr. R. F. Taylor, Los Angeles, secretary.

Fire in Hospital.—Prompt action on the part of the fire department quickly extinguished a blaze that started in a room adjoining the kitchen at the Clara Barton Hospital, San Francisco, December 9. Fortunately no panic ensued.

Annual Meeting and Banquet.—The San Bernardino County Medical Society held its annual meeting at Arrowhead Hot Springs Sanitarium December 13. In the evening a reception and banquet was tendered by the Arrowhead Hot Springs Company.

Shotgun Quarantine.—A shotgun quarantine has been established in the railroad yards at Mammoth on account of small-pox. Six cases have been reported, all among Mexicans. Armed guards are stationed at each end of the railroad yards and no one is allowed to enter or depart.

Vital Statistics.—There were reported 2,153 deaths in the state during November, 1,699 living births and 1,243 marriages, equivalent to an annual death rate of 15.7, a birth rate of 12.4, and a marriage rate of 9.1 per 1,000. Tuberculosis led among the death causes with 329, followed by heart disease with 211; pneumonia with 185; cancer with 117; apoplexy with 98; Bright's disease with 86; enteritis with 82; accidental injuries with 72, and suicide with 52.

Personal.—Dr. Bartolomeo Sassella, Los Angeles, gave a banquet to 30 guests, December 10, to celebrate his restoration to health after an illness of three months.—Dr. W. LeMoyné Wills, Los Angeles, has returned from Europe.—Dr. J. Wilson Shiels, San Francisco, sailed for Tahiti December 28, for a health trip of one month.—Dr. Louis Q. Thompson, Gridley, is ill with septicaemia.—Dr. John J. Tully, Stockton, has gone to New York for nine months.

Annual Meeting.—The Southern California Medical Society ended its semi-annual session at Los Angeles, December 7, with a banquet at the Angelus Hotel, over which Dr. David B. Van Slyke, Pasadena, presided, and Dr. Walter Lindley, Los Angeles, acted as toastmaster. The election of officers, held in the afternoon, resulted as follows: Dr. Howell Tyler, Redlands, president; Drs. Frank Garcelon, Pomona, and William H. Roberts, Pasadena, vice-presidents, and Dr. Henry S. Keyes, Los Angeles, secretary.

¹ G. G. Schacht, f. Bekämpfung des Kurfischertums, THE JOURNAL, Dec. 23, 1905, p. 1966.

INDIANA.

Hospital Opened.—Bloomington Hospital, founded and operated by the Local Council of Women of Bloomington, was opened to the public November 30. The institution has accommodations for 14 patients and Miss Blanche Stoops is the superintendent.

The Trembles.—At the recent meeting of the Indiana Academy of Science Dr. Robert Hessler, Logansport, read a paper on milk sickness, or the trembles, in which he gave an account of a five years' search for the cause of this now practically extinct native disease which has always been so mysterious and was such a terror to the early settlers. The disease was known under the name of "trembles" when occurring in animals, and as "milk sickness" when occurring in human beings after the use of milk from an infected animal, or after eating the flesh. The cause (or rather, what will likely be found to be the cause when the investigation is completed) is an undetermined species of *Streptococcus*—a fungus of the class *Ascomycetes*. The organism was found in the blood of an affected horse, both as free spores and as small yeast-like bodies enclosed in leucocytes. The former disappeared in the course of a few days, while the latter kept on increasing, but later on diminished and disappeared by the time the disease subsided. Another horse similarly affected died and was buried before the true nature of the affection was recognized—before the physician heard of it. All tube inoculations from the blood developed pure cultures; growth develops abundantly on all kinds of media.

MARYLAND.

Personal.—Dr. Benjamin R. Benson, Marble Hill, near Cockeysville, Baltimore County, is ill with appendicitis.—Dr. Charles M. Ellis has been chosen president of the National Bank at Elkton, Cecil County.—Dr. Thomas Warfield Simmons of Hagerstown, who was operated on December 28 for bowel trouble, is said to be sinking.

General Hospital Report.—According to the annual report of the Peninsula General Hospital at Salisbury (Eastern Shore), 345 patients were admitted, 240 of whom were white and 212 free patients; 264 were discharged cured, 19 were not treated, and 7 were unimproved. There were 17 deaths, and 19 remained under treatment at the close of the year. Operations were necessary in 170 cases. There were 29 cases of appendicitis treated, the majority of which required operation.

County Society Election.—The Carroll County Medical Society has elected the following officers: President, Dr. J. Howell Billingslea, Westminster; vice-president, Dr. George H. Brown, New Windsor; secretary-treasurer, Dr. Charles R. Foutz, Westminster, and censor, Dr. J. Clement Clark, Sykesville. The society has had a bill framed for submission to the legislature requiring the county commissioners to appoint a health officer for every district in the county at a salary of \$50 per annum, in addition to the general health officer, who is also to have special charge of Westminster district and to receive a salary of \$150.

Baltimore.

The Bosley Dinner.—Physicians and officials of the health department gave their fifth annual banquet to Health Commissioner James Bosley December 27. Dr. William Royal Stokes was toastmaster.

Osler.—Dr. Osler was to arrive in Baltimore January 5, and during his stay was to be the guest of Dr. Henry M. Hurd at Johns Hopkins Hospital.—A report which originated in a Boston publication that Dr. Osler was thinking of returning to the Johns Hopkins University has been denied by him.

Smallpox Outbreak.—Eleven new cases of smallpox were reported for the week ended December 30. There were 36 deaths from pneumonia and 28 from consumption. The death rate was equivalent to 17.59 per 1,000. The health authorities are much concerned about the prevalence of smallpox, over 80 persons having been sent to quarantine in the past month with the disease or under suspicion. Vaccinators are busy.

MASSACHUSETTS.

Bequest.—By the will of the late Dr. George S. Hyde, Boston, \$50,000 is left to Harvard University Medical School, to be used as the trustees see fit and to become available at the death of the sister and brother of the testator.

Tuberculosis Hospital Report.—Long Island Hospital, Boston harbor, has received since 1900, 894 cases of tuberculosis; 421 patients have died; 23 have been discharged well; 157 are improved, and 293 unimproved. The heavy mortality is due to

the fact that usually only the most advanced cases are received here.

Music in Hospitals.—During January the following concerts will be given by the Hospital Music Fund under the direction of Dr. John Dixwell: January 7, at Home for Destitute Catholic Children; January 14, at St. Elizabeth's Hospital; January 21, at New England Hospital for Women and Children; and January 28, at the Home for Aged Couples.

Awarded High Honor.—The Boston Board of Health was awarded highest honors for its exhibit at the Lewis and Clark Exposition, Portland, Ore. The exhibit consisted chiefly of illustrations and explanations of the treatment of infectious diseases as developed and practiced by the board in Boston. The milk inspector of the board has recently secured convictions of 13 milk dealers for selling milk not up to the standard, of 4 others for selling adulterated vinegar, and one dealer for selling condensed milk adulterated with formaldehyde paid \$100 fine. A local druggist has also been fined \$25 for selling olive oil adulterated with almond oil, his conviction being secured by the State Board of Health.

Tuberculosis Exhibit.—For the success of the state tuberculosis exhibit, to be given in Faneuil Hall the last of December, a strong auxiliary committee has been appointed. The medical men include Drs. William T. Councilman, Harold C. Ernst, Vincent Y. Bowditch, Samuel H. Durgin, James J. Minot, A. G. Getchell, H. Lincoln Chase, Arthur T. Cabot, Arthur K. Stone, Charles W. Page, Edward O. Otis, Frank G. Wheatley and Walker Marley. It is hoped to reach people in every walk of life and to announce to them the fact that there will be such an exhibit. Notices are, therefore, being sent out to those who are in touch with groups of people, such as physicians, clergymen, teachers, charitable organizations, fraternal orders, etc. Young physicians chosen by Dr. William T. Councilman will act as guides.

Hospital Reports.—Worcester Insane Hospital reports that there were admitted during the year ended October 1, 307 men and 264 women, making a total of 1,226 patients resident there at that date, 619 men and 607 women. Of the men admitted 52 had been laborers, 20 operatives, 13 machinists and 12 carpenters. Of the women 49 had been housewives, 32 domestics and 23 housekeepers. Alcohol was the cause assigned for the condition of 77 men and 15 women, while weak constitutions accounted for 23, heredity for 32, sickness for 15, senility for 20, excessive tea drinking for 5, overwork for 1, bereavement for 7, fright for 1 and worry for 5.—Westboro Insane Hospital reports for the same period 538 admissions. Of those admitted for the first time 193 were American born and 134 of foreign birth. There were 133 deaths during the year.

NEW YORK.

New York City.

Pure Food Show.—A pure food show will be held in this city during the entire month of February under the direction of the Retail Grocers' Union. Several associations interested in the pure food movement will hold meetings throughout the month and there will be lectures by pure food experts.

Low Death Rate Again.—The death rate for the week ended December 23 was equivalent to an annual mortality of 17.20 per 1,000, as compared with 19.07 per 1,000 for the corresponding week of last year. There were 82 deaths from violence, while the deaths from contagious diseases were very few.

Personal.—Dr. Thomas Darlington has been reappointed commissioner of health at a salary of \$7,500 per annum.—Dr. and Mrs. William Osler arrived on the *Caronia* from Europe on December 24.—Dr. Samuel F. Brothers has been appointed a chief clerk at a salary of \$3,000 per annum.—Dr. Charles B. Kelsey was recently robbed by his butler of valuable silverware.

New Health Building in Brooklyn. This new building, for which \$295,000 has been appropriated by the board of aldermen, will be erected in Brooklyn and will have 10,000 square feet of space, one-half of which will be for offices. These are to be separate from the general building. There will be an electric light plant and a modern system of ventilating. There will be a separate clinic and isolation wards.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended December 23, 764 cases of measles, with 12 deaths; 312 cases of tuberculosis, with 174 deaths; 300 cases of diphtheria, with 39 deaths; 170 cases of scarlet fever, with 6 deaths; 72 cases of typhoid fever, with 9 deaths; 15 cases of cerebrospinal meningitis, with 15 deaths, and 266 cases of varicella. A total of 1,839 cases and 255 deaths.

Patched-Up Immigrants.—Dr. Maurice Fishberg, special inspector of the immigration service of the United States, who has been visiting European terminals of the transatlantic steamship lines, claims that the "curing" of diseased aliens for admission to the United States has become a great industry abroad. He referred especially to the fixing up of cases of trachoma, and suggests that Marine-Hospital officials should be stationed at all the important immigrant stations of Europe. Dr. Fishberg emphasized the fact that comparatively few fakers succeeded in fooling the inspectors at Ellis Island. The use of adrenalin in cases of trachoma could easily be detected.

Much Milk Destroyed.—In the eleven months ended December 1 the Department of Health collected \$16,000 in fines imposed by the Court of Special Sessions on dealers who offered adulterated milk for sale. In the same period the inspectors poured 38,000 gallons of milk into the gutters as unfit for use, in most instances because it had a temperature of over 50 degrees F. The city daily consumes about 1,500,000 quarts of milk, and only 15 men are employed for the purpose of inspecting this supply. It is estimated from the number of convictions that more than 20,000,000 quarts of adulterated milk have been brought into the city during this period. There were 110,000 samples taken for inspection for adulteration and 6,000 samples were taken for chemical analysis during the two hot months of summer.

Results of Use of Pasteurized Milk.—The records of the Health Department show that in 1892 there were in the city 194,214 children under the age of 5 years and that 18,684 died in the year, the rate being 96.2 per 1,000. Pasteurized milk began to be used and in 1894 out of 256,137 children there were only 16,137 deaths, or 63 per 1,000. At the death rate of 1892 with the present population there would have been 21,640 deaths, whereas there were actually only 16,137, so that apparently there were 8,503 lives saved. Estimated on this basis, it is claimed that there were 4,025 lives saved last summer. On Randall's Island, where the city's children are cared for, the death rate prior to 1898 was 41.83 per cent. After Nathan Strauss established a pasteurizing plant on the island the death rate was cut down to 20.75 per cent. for the past seven years. Last year the rate among these children was only 16.52 per cent. This reduction in the mortality is caused entirely by the pasteurized milk, as other conditions were unchanged.

Hospital Notes.—The annual collection of the Hospital Saturday and Sunday Association was held in the various churches December 21. The association now has 40 hospitals on its list. During the last year the association cared for 53,000 patients, of whom 33,774 were free patients, besides giving medical attention to 114,838 dispensary patients. Plans have been filed for a new six-story and basement building, to be erected in Central Park West for the New York Red Cross Hospital, to cost \$60,000. Thomas F. Ryan has given \$1,000 to the New York Throat, Nose and Lung Hospital to fit up a special department for the treatment of women affected with tuberculosis. The Presbyterian Hospital, in appealing for funds, asks that non-residents contribute because they so often receive aid in times of emergencies, and it is only fair that they should aid in the support of this institution. Several persons whose names have appeared on the list of directors of St. Gregory's Society, organized to manage St. Gregory's Hospital, started by a "beauty doctor," are complaining that their names have been used without authority and that they are not interested in the society or hospital.

NORTH CAROLINA.

Society Meetings. The Randolph County Medical Society has elected the following officers for 1906: President, Dr. S. A. Henley, Ashboro; vice-president, Dr. W. I. Sumner, Randleman, and secretary, Dr. Charles C. Hubbard, Worthville. Dr. Henley presented an instructive paper dealing with the history of the older members of the medical profession of Randolph County. The Buncombe County Medical Society elected as officers for 1906: President, Dr. Thomas P. Chesebrough; vice-president, Dr. William L. Dunn; secretary, Dr. Gaillard S. Timent, and delegates to state society, Drs. Marshall H. Fletcher and Willard P. Whittington, all of Asheville.

Buncombe County Society Banquet.—The tenth annual banquet of the Buncombe County Medical Society was held in Asheville December 18. Covers were laid for 60, a most elaborate menu was served and numerous postprandial speeches were delivered. During the four and a half hours' duration of the fest the orators covered an almost limitless field, ranging from a dissertation on the advisability of standing by the American Medical Association and the revised pharmaco-

peia, the establishing of a public abattoir for Asheville, with sundry suggestions as to hygiene and public health, to a most vivid delineation, in prose or verse, of the supposed and real fancies, weaknesses and frailties of the various prominent members of the profession. Of particular note among the speech makers were Drs. Ambler, Weaver, Fletcher, Calloway, Brown, Sevier, McBrayer, Whittington, Archer and J. Howell Way, the secretary of the state society, who was present as an invited guest of the society. The affairs medical of Asheville and Buncombe County are in most excellent condition. A very considerable portion of the happy state of affairs existing here is attributable to the potent influence of the county society on its membership through its regular semimonthly meetings.

The Indigent Insane.—The governor attended the regular meeting of the directors of the state hospitals recently and caused a complete investigation to be made of the commitment papers and other data bearing on the case of each patient under treatment in the two insane hospitals of North Carolina, and as a result of his careful investigations the absurd charges of the daily press of the state that persons not entitled to receive treatment at the expense of the state were received and treated, were shown to be without foundation. In this connection it may be of interest to note that the question as to the "indigency" of patients treated in the state hospitals at public expense has already been passed on some time since by the Supreme Court of the state and the decision of what an "indigent" is in North Carolina rendered in case Hybart, 119 N. C., 359, in the following language: "The term 'indigent insane,' as used in section 10, article 11, of the Code, includes all those who have no income over and above that which is sufficient to support those who may be legally dependent on the estate." With this decision of the Supreme Court for guidance, the investigating committee reported less than half a dozen of the 2,000 patients as not being entitled to the care of the state in the institutions.

OHIO.

Personal.—Dr. and Mrs. Silas W. Fowler, Delaware, will sail from New York February 8, for the Mediterranean.—Dr. S. E. Allen has been appointed by the board of public service as next health officer of Cincinnati from January 1.—Dr. George P. Tyler, Ripley, has for the third time been appointed chief surgeon of the Ohio River & Columbus Railroad.

Darke County Medical Society.—The medical society of this county held its regular meeting on December 14 at Greenville. The following officers were elected: President, Dr. Matthias M. Corvin, Savona; vice-president, Dr. William Lynch, Greenville, and secretary and treasurer, Dr. Philip Dickes, Greenville. An enjoyable banquet was held in the evening.

Auglaize County Society.—At a meeting of the Auglaize County Medical Society, held at Wapakoneta December 14, Dr. John E. Griewe of Cincinnati, read a paper, "The First Principles in the Treatment of Heart Lesions," illustrated by some twenty diseased hearts. In the banquet in the evening, at which Dr. Charles C. Berlin, Wapakoneta, acted as toastmaster, speeches were made by Drs. Brooks F. Beebe and Charles A. L. Reed, Cincinnati; Dr. Frank D. Bain, Kenton, and Dr. Henry E. Beebe, Sidney, Ohio. Ninety-three per cent. of the physicians of the county are members of the society. This is believed to be the largest proportion of any county medical society in the state.

PENNSYLVANIA.

Physician's Bill Disallowed.—The commissioners of Lackawanna County have refused to pay the bill of \$2,000 of Dr. Alfred Gordon, Philadelphia, for nine days' attendance at court and for giving expert testimony.

Personal.—Dr. Charles D. Schaeffer has been selected acting mayor of Allentown during the absence of Mayor Dr. Alfred J. Yost.—Dr. Howard S. Anders, Philadelphia, delivered an address before the Lebanon County Medical Society on "The Practical Relations of Certain Physical Signs to Prognosis and Treatment."

Pennsylvania Relief Report.—The monthly report of the Employes Relief Fund for the Pennsylvania Railroad Company's lines east of Pittsburg and Erie shows that the payments of benefits for November amounted to \$143,609.91, \$143,739.26 on account of deaths and \$67,870.65 on account of disablement by sickness and accident. The payments thus far are stated to have amounted in the aggregate to \$14,217,475.85, \$5,843,839.64 on account of deaths and \$8,373,636.21 on account of disablement.

Philadelphia.

South Branch Society Election.—Dr. Joseph O'Malley was elected president of the South Branch of the Philadelphia County Medical Society, and Dr. James H. Baldwin was re-elected secretary, at the regular meeting, December 29.

Natural Science Officers.—At the annual meeting of the Academy of Natural Sciences, December 19, Dr. Samuel G. Dixon was elected president; Dr. Edward J. Nolan, recording secretary and librarian; Dr. Charles B. Penrose, counselor for three years, and Dr. Horatio C. Wood, counselor to fill unexpired term.

Personal.—Dr. James Tyson was a guest of honor at a reunion of the District of Columbia Alumni Association of the University of Pennsylvania, held in Washington, December 12. —Dr. George L. Husband fell from a trolley ear December 28 and received a severe injury to his head. He was taken to the Presbyterian Hospital.

College of Physicians Library.—The library of the College of Physicians in this city, one of the greatest medical libraries in the world, contains 73,750 volumes, 8,363 unbound reports and transactions, 19,540 theses and dissertations, and 56,265 unbound pamphlets. The library receives 611 current medical, pharmaceutical and dental journals, including American, English, French, German, Italian, Spanish, Russian and Chinese. The library is open daily to visitors, excepting Sunday and legal holidays, from 10 a. m. to 6 p. m.

Free Exhibition of Tuberculosis.—How to fight consumption will be the principal thought of the free exhibition of tuberculosis, to be held in this city from January 22 to February 3, under the auspices of the National Association for the Study and Prevention of Tuberculosis and the Pennsylvania Society for the Prevention of Tuberculosis. Model tents and fresh-air sanitariums will be on exhibition. Every effort will be made to show the general public how fresh-air treatment may be applied with good results in their city homes. Public lectures will be delivered daily.

Symposium on Exophthalmic Goiter.—A special program has been arranged for the Section on General Medicine of the College of Physicians on January 8. A symposium on exophthalmic goiter will be held, at which Dr. George Dock of Ann Arbor, Mich., will read a paper on "The Clinical Observations on Exophthalmic Goiter (Graves' Disease), with Special Reference to Complete and Incomplete Forms; the Clinical Course and the Treatment"; Dr. James Tyson will discuss the medical treatment, Dr. W. G. McCallum the pathogenesis, and Dr. Joseph C. Bloodgood, of Baltimore, the surgical treatment.

Health Report.—The total number of deaths reported for the week aggregated 491, as compared with 524 reported for last week, and 497 for the corresponding week of last year. There were 136 new cases of typhoid fever reported, which is an increase of 17 over the number reported last week. The principal causes of death were: Typhoid fever, 14; measles, 3; diphtheria, 8; tuberculosis, 61; cancer, 16; apoplexy, 19; heart disease, 49; acute respiratory disease, 73; enteritis, 21; appendicitis, 3; Bright's disease, 43; suicide, 8; accidents, 20, and marasmus, 10. There were 262 cases of contagious disease reported, with 22 deaths, as compared with 274 cases and 29 deaths in the previous week.

VERMONT.

University News.—Dr. John M. Wheeler, Burlington, has been appointed instructor in anatomy in the medical department. —Obstetrics and surgery have been transferred from the second to the third year, and a new compulsory course in experimental physiology has been instituted.

Many Illegal Practitioners.—About 150 physicians in the state are technically illegal practitioners as they have failed to comply with the act of the legislature passed in 1904, which required that all physicians file their licenses with their respective county clerks prior to Jan. 1, 1905.

The Proctor Tuberculosis Sanitarium.—Senator Proctor is in accord with the modern efforts to stamp out tuberculosis. As previously announced, he has, at the request of his children, donated \$50,000 to purchase ground and erect a sanitarium for the treatment of incipient tuberculosis near Proctor. It is to be a state institution, but free of expense to the state, and to this end he has further made an endowment of \$100,000 for its maintenance. The company of which Senator Proctor is president maintains a large free hospital and training school and an emergency service near their quarries at Proctor. The hospital will be located in Pittsford, according to the decision of the state tuberculosis commission.

VIRGINIA.

A Mother at Ten.—A very unusual occurrence has just come to light at Bristol. Sallie Ellison, a colored girl, who was 10 years old last October, has given birth to an eight-pound infant.

Radford Hospital.—La Belle Inn, formerly built as a hotel at Radford, has been leased for a hospital and will be at once put in perfect repair. The hospital is to be operated by McArthur Brothers of New York, the contractors who hold the contract to build 125 miles of the Tidewater Railroad through that section. The institution will not be limited to the employés of the road, but one floor will be turned over to the physicians of the locality.

GENERAL.

Yellow Fever in Cuba.—A few new cases of yellow fever are still being reported. In nearly all cases the infection can be traced to Habana. The immunity requirement has been removed for passengers for southern ports, including Florida. All non-immune individuals, however, are carefully inspected before being allowed to embark.

American Dermatological Association.—At the twenty-ninth annual meeting of the American Dermatological Association, held in New York City, Dec. 28-30, 1905, the following officers were elected for the ensuing year: President, Dr. M. H. Hartzell, Philadelphia, Pa.; vice-president, Dr. Thomas C. Gilchrist, Baltimore, secretary and treasurer, Dr. Grover W. Wende, Buffalo, N. Y. The next meeting will be held in Cleveland, Ohio, in May, 1906.

The National Association for the Study and Prevention of Tuberculosis.—Announcement is made by the board of directors of the National Association for the Study and Prevention of Tuberculosis of the preliminary arrangements for the second annual meeting of the association, which will be held in Washington, May 17, 18 and 19, 1906. Two new sections have been established—one on surgical tuberculosis and the other on tuberculosis in children. The officers of the sections are as follows:

Sociological Section: Chairman, Mr. William H. Baldwin, Washington, D. C.; secretary, Miss Lillian Brandt, New York.

Clinical and Climatological Section: Chairman, Dr. Vincent Y. Bowditch, Boston, Mass.; secretary, Dr. Edwin A. Locke, Boston, Mass.

Pathological and Bacteriological Section: Chairman, Dr. Edward R. Baldwin, Saranac Lake, N. Y.; secretary, Dr. Hugh M. Kinghorn, Saranac Lake, N. Y.

Section on Surgical Tuberculosis: Chairman, Dr. W. W. Keen, Philadelphia, Pa.; secretary, Dr. Robert G. Leconte, Philadelphia, Pa.

Section on Tuberculosis in Children: Chairman, Dr. W. P. Northrup, New York City; secretary, Dr. Roland G. Freeman, New York.

CANADA.

Personal.—Dr. Robert C. Hiseock, formerly of Kingston, Ontario, has been appointed government inspector of health at Lagos, West Africa. —Dr. Charles Sheard, medical health officer of Toronto, has been investigating the smallpox outbreak in eastern Ontario, along with the secretary of the provincial board of health, Dr. Charles A. Hodgetts. Dr. Sheard considers that matters in connection with smallpox in eastern Ontario are in an unsatisfactory state. —Lieutenant-Colonel Carleton Jones, M.D., has resigned his position as assistant port officer at Halifax to become chief medical officer to the Canadian militia stationed at Halifax.

Hospital News.—The Winnipeg General Hospital has received a gift from the Ladies' Hospital Aid of that city of \$1,651. —The total number of patients treated in the Winnipeg General Hospital during the week ending December 9 was 380, of whom 233 were men, 88 women and 59 children. The number in the out-patient departments was 109. —The governors of Notre Dame Hospital, Montreal, held their annual meeting on December 12. The annual report showed a slight increase in the number of patients over the previous year. During the year 2,230 patients were treated, and each of these patients cost the hospital \$1.13 a day. Of the entire number treated 1,363 were men and 927 women. There were 165 deaths during the year, but of this number 53 patients were brought into the hospital in a dying condition. In the different out-door departments of the institution there were 20,991 consultations.

Ontario Smallpox Law.—Dr. Hodgetts, secretary of the Ontario board of health, in view of the prevalence of smallpox in various sections of Ontario, has deemed it necessary to call the attention of the people to the law in connection therewith. This law requires that all children shall be presented for vaccination within three months after birth to an officer appointed

by the municipality, to a medical practitioner, or to the hospital authorities. The law also requires that the child shall be returned for verification on the eighth day. Dr. Hodgetts also calls the attention of the trustees of the various hospitals throughout the province to the fact that not in one single instance are they obeying the law, which requires that they shall keep a supply of vaccine, be prepared to vaccinate the poor free of charge, and all others at a maximum fee of 50 cents. The Ontario law also requires that no pupil shall attend school without first presenting a certificate showing successful vaccination.

College and University News.—The reading rooms in connection with the medical department of Toronto University are in a more satisfactory condition this term than ever before. This is due to the activity of the present student executive committee. All daily papers, leading magazines and medical journals are on file.—The building of the College of Physicians and Surgeons of Ontario in Toronto has been sold for \$100,000. The money thus obtained will be devoted to the purposes of a new building, properly equipped and for the purposes of the college alone.—The medical department of Queen's University, Kingston, Ont., will seek a grant of \$75,000 from the Ontario government for the purposes of a new medical building in connection with that university, and at the same time will ask for an annual grant of \$7,500 to sustain it.—A petition signed by over 1,200 medical students of Canada has been presented to Dr. Pyne, minister of education in Ontario, asking that the government introduce at the coming session of that body the necessary legislation to ratify the Canada medical act of 1902, which is familiarly known as the Roddick bill. All the provinces of Canada have passed this legislation with the exception of Ontario, Quebec and British Columbia. Quebec refused it.

FOREIGN.

Honors for Gutierrez.—Professor Gutierrez, the prominent gynecologist of Madrid, was recently decorated with the grand cross of the Order of Alphonso XII. His friends tendered him a banquet on the occasion.

Borax in Milk.—The county medical officer and the analyst of Middlesex County are soon to submit a report to the Middlesex County Council recommending the total prohibition of the use of boracic acid, coloring matter, or preservatives in any form, in milk, the use of such to be made an offense under the food and drugs act.

Children Excluded from Laundries in France.—A recent decree in France excludes children under 18 from workrooms in which soiled linen is being handled without previous disinfection. This step has been taken on account of the danger of infection from the dust shaken out of the dry soiled clothes while they are being sorted.

Bubonic Plague at Spain.—The steamer *Oropesa*, from South American ports, arrived at Coruna, Spain, December 17. Passengers were not permitted to land owing to the fact that there were 3 cases of bubonic plague on board. The port authorities did not permit the cargo to be unloaded. The steamer sailed for La Pallice, France.

Cremation in Tasmania.—The Tasmanian legislature has passed a bill making it unlawful to cremate unidentified bodies or to practice cremation in cases in which the attorney-general, coroner or police magistrate forbids it. To cremate any body the consent of the chief secretary must be obtained, and the cremation must be done in an approved place.

New Hospital Buildings.—The new buildings of University College Hospital, London, have been completed. Eighty-six additional beds are now available for use. The cost of the rebuilding was defrayed by the late Sir J. Blundell Maple, but the committee appeals for more annual subscriptions to meet the increased expenditures due to the larger number of beds now in use.

Commercial Science and Tariff Reform.—A new museum and laboratories of zoology in connection with the University of Liverpool have been opened recently by Lord Onslow, who said that the blessing which Great Britain enjoyed in the cheapness of food was much more largely due to the inventions of science than to any fiscal relations which could possibly be established with other countries.

The Kussmaul Prize.—In 1903 Professor Czerny of Heidelberg endowed a prize in memory of Kussmaul, the well-known clinician, his father-in-law. The prize consists of a gold portrait medal and 1,000 marks (about \$250) in money. It is to be awarded every three years, as already mentioned in

these columns, for the best therapeutic achievement (*therapeutische Leistung*) first published in German literature.

Special Course in Hygiene.—The University of Lyons, France, has inaugurated a special course in hygiene entitling to a diploma. The final examinations in chemical, microscopic and bacteriologic technic as applied in hygiene will include practical tests supplemented by oral examination in public and school hygiene, in sanitary engineering and legislation and epidemiology. The *Semaine Médicale* states that medical students who have passed four examinations and duly qualified French and foreign physicians are eligible for the course.

Research on Sleeping Sickness.—About \$30,000 has been appropriated by the German government to defray the expenses of a scientific mission to Eastern Africa to study sleeping sickness. The party will include an expert protozoologist and a bacteriologist with a physician familiar with the conditions in Eastern Africa. The expedition will probably require 18 months for the research. Sleeping sickness is not prevalent yet in the German colony, so the party will probably locate in the adjoining Uganda district. The *Deutsche med. Wochs.* hints that Koch may head the expedition.

Gloomy Hospital Outlook in London.—In a recent issue, *Hospital* states that many London hospitals, in consequence of overbuilding and other forms of ill-considered expenditure, are extremely embarrassed financially. They are in the custom of continually exceeding their income, trusting to a "wind-fall" or to a special appeal to reduce the accumulated debt. As a result the general outlook is gloomy, and several institutions are contemplating closing some of their wards. The announcement has been made that in London there are 1,000 hospital beds empty owing to lack of funds.

International Congress of Alimentary Hygiene.—A society for scientific alimentation has been organized in France, and it has issued an appeal for an international congress to be held at Paris February 26 to March 6, 1906. It will be divided into the two sections of scientific researches and their practical application in daily life. The society proclaims that the masses do not obtain as much nourishment from their food at present as they should for the expense, and the congress is summoned to discuss the various aspects of the subject from different points of view, especially the sociologic and economic.

Imprisoned for Fraud.—A certain physician took a position with a Leipzig sickness insurance society when its medical officers had resigned in a body and the *Leipziger Verband* was warning others against accepting a position with the society. He was given \$1,500 by the organized physicians to withdraw after they had made a satisfactory agreement with the society. He took the money, but failed to state that he had already entered the service of a similar society in a nearby city in the same role. The Leipzig court condemned him to two months' imprisonment for obtaining money on false pretenses.

Success of Vaccination of Cattle Against Tuberculosis.—The *Presse Médicale* of December 6 reports the findings when the calves vaccinated according to von Behring's method a year ago at Melun, France, were slaughtered. Vallée had the experiments in charge, and used 40 calves, keeping half of the number for controls. Ten other calves in an infected stable were also vaccinated at the same time and none of these had contracted tuberculosis. The great contrast between the advanced, diffuse lesions of the controls and the circumscribed relics of the inoculation in the animals inoculated was most striking. The report confirms the results published in Germany.

The Cocain Habit in India.—It is reported that the cocain habit is spreading to an alarming extent among the natives of Upper India. The Mahometans in the Benares division recently sent a deputation to invoke the aid of the government in preventing the sale of cocain to young men and boys. An inordinate consumption of this drug has also been reported from Cawnpore, Lucknow and other parts of the United Provinces, and a bill to amend the excise act has been laid before the provincial legislative council, which, it is hoped, will diminish the number of victims of this pernicious habit. Eradication of the evil by legislation has been tried in Bombay, Bengal and Burma.

Action of Radium in Hydrophobia.—Tizzoni's interesting experimental research with radium in rabies and vaccination against the disease were mentioned in the last volume, page 1334. The Italian authorities are so impressed with the possible value of his work that funds have been appropriated to enable him to purchase the quantity of radium necessary to apply the radium treatment to man. He thinks that about

6,000,000 radioactive units will answer the purpose, judging from the effects on rabbits of 100,000 units. An interesting feature of his research is that the effectual therapeutic dosage can be estimated from the radioactive properties acquired by the part treated. The Roentgen rays do not influence rabies.

Prize for Calmette.—Professor Calmette of Lille, director of the Pasteur Institute there, and well known for his researches on antiserums for snakebites, has been awarded the Audiffert prize given by the Paris Académie des Sciences Morales et Politiques. This prize of 15,000 francs (\$3,000) is awarded to recompense devotion—"les plus beaux, les plus grands dévouements"—of any kind. It was through Calmette's efforts that the first antituberculosis dispensary was founded, and the one thus started has proved a model in every respect. Its work is supplemented by extensive oversight and assistance of the tuberculous at their homes. Another feature of the dispensary is the official sent to the factories and elsewhere to discover incipient cases of tuberculosis even before the subject himself realizes that he is infected.

Plague in Japan.—Passed Assistant Surgeon Moore reports from Yokohama that plague continues to spread in Osaka and Kobe. In the former city 18 probable cases, with 14 deaths, occurred during the period from October 27 to November 15. In Kobe for the period from November 8 to 15, 7 cases were reported. A plague-infected rat was discovered recently in Tokio. Thus the present plague situation in Japan justly gives rise to considerable apprehension, tempered, however, by the recollection of the success which has attended the efforts of the authorities in coping with previous outbreaks of this infection. It again may be noted, says Dr. Moore, that a large proportion of Japanese emigrants from Hawaii, even of those taking passage at Yokohama, pass through Kobe and Osaka en route. The situation seems to demand extraordinary precautions.

Results of Antityphoid Vaccination.—The first reports have been received from the German troops who were vaccinated against typhoid before leaving for their station in southwestern Africa, as described in *THE JOURNAL* at the time. Out of 424 cases of typhoid fever reported from the station, 100 of the men had taken the preventive vaccination. The protection conferred is thus not absolute, but the vaccinated cases were distinguished by the mildness of the disease, the absence of complications and the small mortality. The *Deutsche med. Wochts.* for November 16 tabulates the details of the cases among the vaccinated and the unvaccinated for comparison, noting especially the preponderance of extremely light cases among those who had been vaccinated more than once. The total mortality was 4 per cent. of the 100 vaccinated men and 11.1 per cent. of the others.

The Medical Curriculum in Melbourne.—The following amendments in the medical curriculum at the University of Melbourne, which have been under discussion for some time, have been decided on: 1, The teaching of organic chemistry in the first year, to enable students to understand pathology; 2, the teaching of anatomy and physiology in the second year, as a groundwork for surgery later on—the work of the second year to be confined to anatomy and physiology; 3, the commencement of hospital and surgical work in the third year; 4, the lessening of the number of examinations by cutting out the examinations at the end of the second and fourth years, it having been found that the practice of holding the examinations in pathology at the end of the fourth year resulted in the neglect of medicine and surgery until the fifth year; 5, in future, students must attend hospitals for the study of all diseases, instead of two optional diseases, but this work may be done after examination if the student wishes.

Plight of the Medical School at Rome, Italy.—All medical visitors to Rome have been impressed with the imposing Policlinico, which has been fifteen years in building and has cost already more than four million dollars. It was designed by Baccelli and is regarded as a triumph of medico-educational architecture. The wards have been occupied by the sick for several months, but the educational equipment has been neglected, the government postponing from year to year the appropriation of the quarter of a million required to furnish and equip the lecture rooms, laboratories, etc. The Policlinico is located on the outskirts of the city, and the medical students receive part of their instruction there, and then have to go to the other great hospital on the opposite side of the city and elsewhere for the rest of the teaching, hours being thus wasted in transportation besides the considerable expense for car fare. The students have finally rebelled and gone on a strike, the situation being quite serious, according to a letter from Rome in the last *Lancet*, as the faculty are helpless in the matter.

Dismissal of Suit Against Two French Physicians.—The long litigation in which Drs. Séné and Chiché of Bordeaux have been entangled since 1899 has finally resulted in their honorable acquittal. Dr. Séné ordered the removal to the quarantine station of a pregnant woman who had arrived from an infected port and presented symptoms of yellow fever in an advanced stage. Dr. Chiché had charge of the case, but was unable to save the patient. Her father sued the two doctors for damages, alleging malpractice, neglect, etc. He demanded that the body be examined, when it was found that the seven-months' fetus had been expelled by postmortem gas formation. The newspapers made a sensational affair of this coffin birth, and for six years the two doctors have been summoned from court to court and subjected to endless annoyance simply because the first had done his duty in protecting the public health and because the second had been unable to save a moribund pregnant woman. Our French exchanges comment with considerable seriousness on this case and the possibilities confronting the custodians of the public health which it suggests.

Seventh International Congress of Working Men's Insurance.—For the first time in the history of these congresses the fraternities, lodges and other mutual benefit and governmental insurance societies took a prominent part in the proceedings of this large and animated congress. This is important in view of the statement by one of the speakers at the recent Tuberculosis Congress, that when such societies once wake up to the fact that it will be to their direct pecuniary benefit to stamp out tuberculosis among their policy-holders, that a great onward stride will have been taken in the extermination of the scourge. The mutual benefit societies are gaining ground in every country, and their membership is becoming enormous. Once enlisted on the side of preventive medicine, their influence would be far-reaching. The proper remuneration of the medical officers of these and similar insurance societies is one of the vital questions abroad. As at present conducted, it was said, the medical official is the only one who does not profit by the mutual benefit plan or governmental insurance. An editorial in *THE JOURNAL* for December 23 depicted the wide scope of insurance of work men and women against sickness, accident and old age as it has developed in recent years in Europe.

Fourth International Congress of Insurance Examiners.—This congress will be held at Berlin Sept. 11 to 15, 1906. The subjects announced for discussion are early signs of a tendency to tuberculosis; obesity in relation to life insurance; influence of syphilis on length of life, and the vaccination clause in insurance contracts; also the influence of accidents in case of internal disease; acute aggravation of insanity through accidents; influence of injuries on organic spinal disease and mental derangements, and the criterion of the aggravation of all functions (nervous diseases, neurosis) through accidents. Reports are being prepared on all these subjects in each country to be represented and the minutes of the proceedings will be sent to members in English, French and German. The meetings will be held in the parliament buildings. The membership fee is 16 marks (\$4). The organizing committee includes fifty-nine of the prominent physicians of Germany, and an urgent appeal is made to all examining physicians for insurance companies to take part in the congress either personally or by subscription alone, which will entitle the member to all the transactions, etc. Contributions for the congress may be in English, French or German, but not to exceed 8 to 16 printed pages. They should be accompanied by a summary not more than a page in length. Further details can be learned on application to the general secretary, Dr. A. Manes, Berlin W. 50, Spichernstrasse 22.

Smallpox and Yellow Fever in Brazil.—Consul Aymes reports that there is a great deal of yellow fever in Para and that the epidemic of yellow fever is assuming serious proportions. He states that every year during the last four months of the year—the dry season—there is a marked increase in the number of cases of both smallpox and yellow fever. This year the season is unusually dry and hot, and both diseases have assumed the character of an epidemic, and Mr. Aymes reports that it is becoming evident that the smallpox epidemic is extending to the neighboring towns and villages. His attention was first called to the severity of the nascent epidemic late in September. Smallpox patients are isolated in a special hospital, which is now accommodating twice the number it was built for. Temporary wings of rough lumber are being erected and a second hospital has been taken for the shelter of smallpox patients. As there is no system of registry of cases of contagious and infectious diseases, it is difficult to obtain exact statistics. There is also, he states, a large and increasing num-

ber of cases of typhoid fever in this city. The yellow fever and smallpox patients are not confined to the lower or even to the middle classes, but all alike suffer. Foreigners in particular are liable, and scarcely one in Paris has escaped one or the other disease; the number of deaths among the foreign colony is large. The rains will not set in before the middle of December; when they do begin it is said that in both diseases the cases rapidly begin to diminish in numbers and intensity, particularly smallpox.

New Isolation Hospital at Rotherham, England.—The new Rotherham Isolation Hospital, the foundation stone of which was laid nearly two years ago, was opened formally December 7. The total expenditures, including land, building and furniture, were a little over \$95,000, and 33 beds for male patients and 33 beds for female patients have been provided. The buildings consist of an administrative and six other blocks, including the laundry, disinfecter, and discharge lodge, and the observation ward. Separate provision has been made for acute and mild cases of scarlet fever. This rapid conversion into practice of the very modern conception that the aggregation of severe and mild cases of scarlet fever is dangerous is a notable and specially creditable feature. The distribution of beds is of some interest: 18 beds are assigned to severe scarlet-fever cases, 16 to those of milder type, 14 each to diphtheria and typhoid, and 4 beds in two separate wards to observation cases. The buildings lie on elevated ground, about one and one-fourth miles from the center of the town, and have five and three-fourths acres of ground devoted to them; the different blocks are, therefore, well separated. All the wards face southeast, and each is provided with a glass-covered veranda for the use of convalescent patients; each block, moreover, forms a complete and independent unit by itself, being provided with its own kitchen, bathrooms and stores. The ventilation is natural fireplace ventilation, supplemented by outlet shafts in the ceilings, and grids under each bed. The scarlet-fever patients have an allowance of 2,106 cubic feet of air space, and 156 superficial feet floor space, while the diphtheria block is provided with a small operating theater.

To Collect Statistics of Syphilis and Alcoholism.—The Paris Académie de Médecine has been discussing the question of compulsory declaration by physicians whether alcoholism or syphilis was the direct or indirect cause of death. A number of speakers said that the defective statistics gathered by such means did more harm than good. The figures showing that only 145 deaths had occurred in Paris last year from alcoholism—as stated in the official statistics—were extremely misleading to laymen. A resolution was finally adopted by the academy to the effect that it would be desirable to add to the present death certificates the following lines on a detachable coupon:

Alcoholism	{	is the cause	{	principal	{	of death.		
Tuberculosis							{	accessory
Syphilis								

The physician signing the certificate should underline the words that apply to the individual case. This resolution was supplemented by another from which much more is hoped, namely, that medical societies and associations of surgeons, obstetricians, alienists and others take up the matter and request those of their members willing to take a personal interest in the question to compile personal statistics, to be published ultimately by the organizations and filed for reference. Personal statistics collected by physicians at the head of hospitals and asylums, or others having a large experience, will prove a most valuable aid in the study of the prevalence and ravages of these modern scourges. Raymond's experience has been that alcohol was the principal etiologic factor in two-thirds of 2,000 various nervous or mental affections under his observation last year, and Fernet's percentage at the Beaujon was the same, both for men and for women.

A Congress to Discuss Measures to Restrict the Illegal Practice of Medicine. The French for some time have been organizing an anti-quackery congress. It has been postponed from time to time, as has been mentioned in these columns, but the date is now definitely settled for April 30 to May 3, 1906, at Paris. The official title of the congress is "Congrès pour la Répression de l'Exercice Illégal de la Médecine." A number of prominent physicians and lawyers are collecting material for communications, twenty-five subjects having been appointed on the order of the day. These include: 1, Illegal practice by bone-setters and empirics dealing in magic; 2, by quacks, magnetizers and hypnotists; 3, by lay or clerical persons under pretext of charity; 4, by members of societies for aid of the sick or invalids; 5, by nurses or attendants on the sick. Massage is the sixth subject; what it is, its dangers, and what schools

of massage now are and what they should be. Mesnard of Paris will deliver the address on this subject. The seventh is the illegal practice of medicine by chiropodists, manicurists, hair-dressers and barbers. It will be presented by a physician and a pharmacist. Subject 8 is the practice of medicine by druggists. Then follow illegal practice by opticians, by medical electricians, by dentists, by midwives, by medical students, and by foreign physicians. The misleading effect of the title of doctor assumed by pharmacists, health officers and others will be discussed. Dr. Sentourens will present the subject of the co-operation of physicians in fake establishments or money-making schemes, "covering" as it is called abroad, sheltering the scheme or the quack under the medical diploma. The rôle of the press in regard to the illegal practice of medicine will be discussed by two lawyers, as also the subject of the pseudo-scientific articles written by unqualified persons on medico-pharmaceutical subjects for advertising purposes. Professor Folet of Lille will discuss the illegal and charlatanesque practice of medicine by advertising, and Dr. Lerédde of Paris will speak on the means of warning the public in regard to the dangers of the illegal practice of medicine. Bardet will discuss the psychology and the economic aspect of the causes leading to the illegal practice of medicine. Two prominent lawyers will discuss the French laws affecting the practice of medicine and their inadequacies in many points, with suggestions for improvement. The powers and action of various medical organizations will be discussed by Dr. Maxwell, a medicolegal expert. The creation of a central office for the campaign against irregulars of all kinds will be suggested and urged by Dr. Ch. Levasort, 2 Place des Vosges, Paris, who is the general secretary of the congress, to whom all communications should be sent. The membership fee for the congress is 20 francs (\$4). Communications for the congress in foreign languages must be accompanied by a summary in French. It is proposed to appoint a permanent committee at the close of the congress which will strive to have the various resolutions that may be passed by the congress carried into practical realization. Brouardel will preside at the congress, but Duchesne is chairman of the committee of organization.

Compilation of Cancer Statistics.—The best wording for collective inquiry circulars to be sent to physicians for cancer statistics is being earnestly discussed in Germany. The circular issued by the Berlin headquarters of the Prussian cancer research society is not accepted by the Wurtemberg committee. The points that should be brought out in the statistics, the latter committee states, are age, sex, standing of the family, race, nationality, occupation, social position, income, number of births, heredity, relation to other affections, constitution, contact with cancer subjects in the closest and widest sense, conditions of house and soil, geographical and chronological differences, city and country, localization, differentiation from other tumors and duration of the affection. The mortality figure must be the basis of the percentage. This figure is derived from the proportion of the dead to the corresponding living. This proportion is the only one of any value for statistical purposes. City and country should be listed under separate headings. The "age structure" (*Altersaufbau*) of the living should always be borne in mind, and any neglect of the living totalities and of the age structure is certain to entail error. The average age at death varies with the age structure of the living, and is totally unadapted for purposes of comparison. The mortality figure can be compared only with like figures. The living and the dead must be counted on the same plan. Clinical statistics are too apt to be a collection of "interesting cases," and to be restricted to certain classes of society. Collective inquiries are liable to result in a mere collection of such clinical statistics, owing to the lack of participation by all physicians. In such case they are merely a mass of casuistics, of no value for statistical purposes. Mammary cancer and uterine cancer should be classed separate from those of other localization. Sarcomata can not be effectually separated from carcinoma in the death certificates. Geographical distribution of cancer is not available for statistical purposes, as the various countries differ in their methods and in the exactitude of their vital statistics. Aliens should be classed apart. Comparison between small districts with different kinds of soil is a promising field, but it requires larger material, improved methods of vital statistics in the country and also a knowledge of the age and social structure of the living. Statistics in regard to cancer houses should mention the number, age structure and social condition of all the inhabitants. It is of little purpose to determine the occupation of those dying of cancer unless the occupations of the corresponding living are known. Con-

jugal cancer should be listed on the same plan as cancer generally, especially regarding the age of the surviving consort. In regard to heredity, uterine cancer should be classed separately. When it is not possible to base comparative statistics on the years when the patients were under observation, it is recommended to compare the heredity in regard to cancer of the subject's own family and that of the consort. It does not prove anything that the parents of a cancer subject reach a higher age, as they were, on an average, 30 years old when he was conceived, and have this advantage over him of these years. Life insurance statistics mention heredity and degeneration much more frequently than it is heard of among the poorer classes, whose generations succeed each other without much medical oversight. Another source of error in compiling statistics from the life insurance books is that the parents and other members of the family are usually living at the time the applicant is examined. The study of two successive generations is the ideal research in heredity. The relations between cancer and tuberculosis should be studied on the same principles as the heredity of cancer. The municipal and state statistics should be utilized, especially those relating to dwelling houses, occupation, etc. The Swiss methods of vital statistics are held up as a model for further improvement. Much work will have to be done in the way of educating official statisticians for classification of deaths and of the living by occupations, etc. The suggestion is made that a central bureau of information be organized to which physicians making a serious study of cancer can apply, and which will warn against compilations or articles based on defective or unreliable data. The co-operation of all national and local cancer research committees is desirable. Some can devote their energies to certain aspects of the question, while others can study other phases. The Bavarian committee has called for a report on the last day of 1905 in regard to every cancer patient who has died or been dismissed from treatment during the year and not reported to the committee in previous inquiries. Dr. Kolb, Konradstrasse 9, Munich, Germany, is the secretary of the Württemberg cancer research committee.

LONDON LETTER.

Milk Preservatives.

The question whether or not the use of preservatives in milk is illegal is proving a most difficult one in the law courts, as conflicting evidence is given by the physicians summoned on either side. Thus a dairy company was recently charged with selling milk containing 4.8 grains of boric acid to the pint. The local health officer said that boric acid in milk is injurious to health. On the other hand, Dr. R. Hutchison, the well-known authority on foods, stated that boric acid to the extent present is not injurious to health. The case was, therefore, dismissed. In another locality an exactly opposite decision was given. A dairy farmer was charged with selling milk containing only 1½ gr. per pint. Professor Kenwood and the local health officer stated that the use of boric acid in milk even in small quantities is injurious. A fine of \$8 and \$20 costs were imposed. The necessity for some action of the government to settle the question of the legality of milk preservatives, the use of which has greatly increased in recent years, is pressing. The county council of Middlesex has adopted resolutions asking that the local government board and the board of agriculture and fisheries decide that the use of any preservative or coloring matter or preservative of milk offered for sale be constituted an offense under the "Sale of Food and Drugs" act.

The Crusade Against Consumption.

It is felt that in the crusade against consumption success depends on the systematic action of every county, group of counties, or great centers of population, throughout the land. Systematic action is being put in force in ten counties and in four of the largest provincial towns. The metropolitan county of Middlesex, with a population of about a million and an annual death roll of over 1,400 persons from tuberculosis, has as yet made no organized effort for the cure and prevention of the disease. An appeal for funds to found an open-air sanatorium has been made. This is signed by many influential persons, including the bishop of London, the Roman Catholic archbishop of Westminster, the chief rabbi, and Sir William Broadbent. It is intended that the sanatorium shall be placed in or near the county; that sufficient land shall be attached to it to provide employment for convalescents, and for those patients capable of doing anything; that it shall accommodate both sexes, and that the buildings shall be of the simplest and least expensive character. The patients' sleeping accommodation will be detached from the administrative blocks and so constructed that the air can have free and direct access in all

states of the weather without exposing the occupants to draught or wind. It is thought that there ought not to be less than 100 beds, which would admit for treatment each year about 350 patients. The estimated cost of the land, building, furnishing, lighting, etc., is \$150,000.

Aniline Black Dyeing.

As aniline black dyeing has in many instances proved injurious to health a memorandum has been issued on the subject by Dr. Whitelegge, chief inspector of factories, containing provisions for the protection of the health of those engaged in the various processes of mixing, preparing, "aging," chroming, washing off and drying involved in the preparation of aniline black. Toxic symptoms are due mainly to inhalation, but also to absorption through the skin and to decomposition of the salts when the material is allowed to dry on the clothes. A greyish or bluish coloration of the lips with a tendency to distension of the small veins and pallor of the face are produced. In those who have worked long with aniline gastric disturbances are common. Chronic acid is also used in the process of aniline black dyeing and may cause injurious effects—ulceration of the skin, frequently commencing after an abrasion. The roots of the nails, the creases over the knuckles and the skin between the fingers are the parts most usually attacked. This ulceration may penetrate to the bone and lead to loss of the nails and to deformity of the finger joints. The danger is greatest in those employed in handling the crystals and in boiling the solution; and among these individuals perforation of the nasal septum has been observed. In some persons a papular eruption is produced on the hands, especially round the knuckles, on the palm, in the fold between the thumb and first finger and about the wrists and forearms. Constant contact with the solution causes the papules to burst, leaving a chronic ulcerated condition. The following provisions are recommended by Dr. Whitelegge: 1. Exhaust ventilation by means of ducts and hoods in connection with a fan (a) over each preparing machine; (b) at the point where dust is produced in chroming; and (c) in the process of steaming. 2. A meal room for the use of the workers. Food must not be introduced, prepared or taken elsewhere. 3. Ample washing accommodation. 4. No person to be allowed to come into contact with bichromate who has any rash or ulcer the result of his work. 5. The person weighing out the bichromate crystals or lading out the prepared aniline liquor should be provided with and should wear rubber gloves.

Security of Tenure for Health Officers.

In the rural and smaller urban districts the health officers often are hampered in the performance of their duties by the fact that their appointment is not a permanent one, but has to be renewed at intervals varying from one to five years. If they recommend measures which prove unpopular, in consequence of expense, they endanger their reappointment. The health authorities in these districts are far from progressive and are often loath to carry out sanitary reforms, and this insecurity of tenure fosters their reluctance. It has long been thought that the remedy for this condition is the abolition of periodical re-election of health officers and making the sanction of the government necessary for their dismissal. A bill with this object was introduced into parliament during the last session by the British Medical Association. A deputation of members of the Association of the Incorporated Society of Medical Officers of Health and of the Sanitary Inspectors' Association has now waited on Mr. Gerald Balfour, the president of the local government board, in order to discuss with him the provisions of the bill which it is proposed to introduce next session in its present form, or with amendments. Mr. Balfour, while admitting that the tendency of the bill is in the right direction, said that there are objections to giving permanency of tenure to all health officers. The reform is certainly urgently required.

The Proposed Amalgamation of the London Medical Societies.

A special meeting of the Royal Medical and Chirurgical Society has been held to consider the report on the union of the medical societies (previously referred to in THE JOURNAL) as adopted at the general committee of representatives of the societies. The president, Sir R. Douglas Powell, dealt with the present position of the society and pointed out that one of its great cares was the library which had been most successfully built up during the 100 years of the society's existence. This valuable possession, therefore, should be most carefully safeguarded. A resolution in favor of the amalgamation scheme was carried. At the Clinical Society a similar resolution was adopted.

Pharmacology

The Testimonial.

The testimonial is often referred to as one of the factors that has brought about the decadence of therapeutics. In the past many testimonials to the virtues of proprietary remedies were given because the physician really believed that the drug would do just what he testified it would do. Others gave testimonials because their minds were preoccupied with sundry matters, while a persuasive representative of the "proprietor" induced them to sign a statement which they later regretfully realized was not strictly correct and which placed them in a false position. Still others signed testimonials out of pure charity. A bankrupt or health-broken physician whom they knew as a "good fellow" was endeavoring to make a living out of the manufacture or marketing of a seemingly harmless prescription under a new name. To help him they gave a testimonial, feeling that the good deed of brotherly kindness outweighed the indiscretion. Yet it often has happened that even this testimonial has in after years turned up in the possession of another at most embarrassing junctures and has been a very plague to the giver. Lastly, many physicians have given testimonials because they received a *quid pro quo*, either cash, a discount on some article of medical use, or for some other consideration. Putting it squarely, a certain proportion—not large, to be sure—of testimonials have been bought and paid for. This malign leavening of the great mass of testimonials constitutes a good reason for always refusing to give one to anything or to anybody. Only a rigid adhesion to this rule will enable one who is careful of his honor to avoid unpleasant consequences. To aid the needy widow of a reputable physician a well-known doctor some years ago gave her a testimonial regarding a certain spring water out of which she was endeavoring to make a living. A few years later the spring passed into other hands, the testimonial was found, and the new proprietors published it widely in the daily press. At a most inopportune moment this was made the basis of formal charges of unprofessional conduct by another medical man who knew nothing of the antecedent circumstances. The giving of testimonials, no matter what the circumstances, may expose the giver to unpleasant gossip among those of his fellows who are not his intimates. Sooner or later every testimonial is likely to find its way into print, and then a little circular or booklet it appears on the desk of every practicing physician in the land. Even now some men in good standing are being embarrassed by the wide circulation of a pamphlet containing their unwary commendations of a proprietary remedy. "It is highly reprehensible for physicians to give certificates attesting the efficacy of secret medicines, or other substances used therapeutically," is not by any means the least important sentence in the Principles of Ethics of the American Medical Association. The testimonial is unwise, unsafe, and the sooner it is "out of date" the better. Leave it to the "patent medicine" makers and their patrons, where it belongs.

Another Death from Kopp's Baby Friend.

In THE JOURNAL, Nov. 25, 1905, page 1678, was published a report of a case of poisoning in a child from a "patent medicine" known as "Kopp's Baby Friend." At that time we had the preparation analyzed, and the analysis showed that it contains in 100 c.c., 0.0719 gm. morphin sulphate; approximately 1/3 of a grain in one fluid ounce. A death is now reported from Baltimore from the use of this preparation. The following verdict was rendered by the coroner:

BALTIMORE, December 18.
George William Franklin Lanester (white), aged three months and fourteen days, died December 15, at 25 Frederick avenue, extended, on account of a dose of Kopp's Baby's Friend, given by his mother, while suffering with indigestion. Inquest at the Southwestern Police Station, December 18, 1905. The jury warns the public not to use "Kopp's Baby's Friend."

C. FRANK JONES, Coroner.

The state's attorney, Albert S. J. Owens, issued a statement to the public, which he closed as follows:

This case emphasizes the necessity of the refusal by the public to use any remedy not prescribed by a practicing physician, and at the same time the urgent need of a law prohibiting the sale of any patent or proprietary medicine containing any deadly drug unless the label is labeled "poison."

The Danger of the Secret Nostrum.

It is interesting to examine the formula of "Ayer's Cherry Pectoral," which is now published by the makers. According to their statement each fluid ounce contains:

	Grains.		Grains.
Wild cherry	6	Bloodroot	2
Grindelia robusta	4	Rio Ipecac	2
White pine	4	Citric acid	2
Senega	4	Heroin	1/6
Terpin hydrate	4	Alcohol (minims)	60

with glycerol and syrup.

It will be noted that the principal part of the preparation is a "culling of simples," but two ingredients signify much more; they are substances of specific and marked physiologic action and of recent introduction. Ayer's Cherry Pectoral has been on sale for many years; its manufacture antedates that of terpin hydrate and heroin. It is obvious, therefore, that the composition of the remedy has been changed. In this case the change may be a beneficial one, but instances have been cited in which a particular drug has advanced in price and something cheaper has been substituted. This indicates the greatest danger of secret remedies; there being no control or publicity, there is no responsibility or guarantee of uniformity. Voltaire's dictum, "Whatever is secret must be doubtful," may be appropriately applied here. The question that will suggest itself is whether or not any other active drugs were used instead of terpin hydrate and heroin in the earlier manufacture of the preparation.—Dr. Henry Leffman, Philadelphia.

The South Carolina Journal Stands for Honest Pharmacy.

The following leading editorial appears in the *Journal of the South Carolina Medical Association*. It is self-explanatory, indicating the plain stand of that journal on the question of honesty in pharmacy:

In the September issue of *The Journal of the S. C. Med. Assoc.* appeared an endorsement of the *American Medical Journalist* which was equivalent to an attack on the policy of the American Medical Association in fighting the patent and proprietary medicine combination. The *American Medical Journalist*, which is evidently published by and in the interest of the manufacturers of proprietary medicines and nostrums, has taken full advantage of its opportunity, and has reprinted this endorsement and circulated it broadcast, making it appear that we have severed our allegiance to the righteous cause championed by the American Medical Association. It is a matter of deepest regret and mortification to the editor that the item referred to should have been allowed a space in the journal by the associate editor during the absence of the former on his summer vacation, and he wishes it clearly and distinctly understood that his policy of antagonism to nostrums and proprietary compounds has not been altered by a hair's breadth. *The Journal of the S. C. Med. Assoc.* will continue to aid in the great fight, and will always rejoice to give publicity to whatever may help to remove the scales from the eyes of the multitude of physicians who are blindly aiding and abetting the gigantic nostrum fraud which attempts to masquerade in the guise of honesty and truth. We are thoroughly in sympathy with the American Medical Association and will welcome every opportunity to render whatever assistance may be in our power.

The Editor and His Honesty.

"In a recent issue of one of the larger medical weeklies—a publication which expressed, through the correspondence of its owner and publisher, an exceeding thoughtfulness for the nostrum manufacturer and his delectable business of exploiting the physician and the patient—appeared an editorial dealing with the subject of those qualities which should be possessed by the ideal medical editor, and inferentially suggesting that very few such eminent editors are known to exist, which statement is probably correct. . . .

"The catalogue of virtues and qualifications of which the happy ideal medical editor should be possessed includes everything desirable except one—honesty. . . . Simple, homely honesty, we are beginning to be taught, is quite commonly ignored in high places. There exist throughout this country scores of medical journals edited by men whose lack of liter-

any apprenticeship and editorial training is demonstrated on every page? He might well have added that their commercial instinct, their disregard for any ethical, professional or humanitarian consideration, and their absolutely cold-blooded greed, are demonstrated with equal clearness on almost every page.

"The ideal, or, if you will, the quite competent medical editor must recognize that his principal duty is the ignoring of self-interest in his reviews and criticisms," etc. (italics ours). Exactly. But let him not ignore his self-interest so far as the advertising pages are concerned. Let him accept money from any unscrupulous person who may wish to exploit the medical profession and delude its members into using some worthless nostrum. Let him sit dignified in the editorial chair and ignore the fact that such things as advertising pages exist, and that they not infrequently do great harm to that profession which it is his to serve and guide. It is undignified to take cognizance of such mere business details as advertising pages when learned editorials are to be written and published. It is undignified to observe that the medical profession have been made fools of, for a generation or more, by unscrupulous 'manufacturers.'

"It is dishonest for medical journals to advertise dishonest or fraudulent articles or such things as do an injury to the public and to the medical profession. This ideal editor would do none of these things. No, indeed! Not because he would ignore self-interest, but because he would have it cultivated to the very highest degree."—*California State Journal of Medicine*, November, 1905.

Resolutions Indorsing the Fight Against Nostrums.

At its December meeting, the Omaha-Douglas County Medical Society adopted resolutions commending THE JOURNAL for its educational campaign against nostrums, indorsing the work of *Collier's Weekly* and the *Ladies' Home Journal* in exposing nostrums and the pernicious methods of advertising them, and pledging the support of the members to these periodicals.

The Montgomery County (Pa.) Medical Society, at a meeting held December 13, passed resolutions expressing appreciation of the forceful and truthful presentation of the evils of the nostrum business by THE JOURNAL, *Collier's Weekly*, *Ladies' Home Journal*, *Farm Journal*, and *Marine* (Ill.) *Telegram*, and declaring that the medical and lay press should put forth their best efforts to destroy this dangerous traffic.

Similar resolutions were passed by the Fairfield County (Ohio) Medical Society, by the Berks County (Pa.) Medical Society, and by the Newton County (Miss.) Medical Society.

CHICAGO, Dec. 22, 1905.

The Board of Trustees of the American Medical Association.

Gentlemen:—The Douglas Park Branch of the Chicago Medical Society has directed me to express its thanks to THE JOURNAL of the American Medical Association and to the Council on Pharmacy and Chemistry for the active part which THE JOURNAL is taking in the present exposé of proprietary nostrums. We also wish to assure you of our continued interest and support in this movement, and trust that it will be productive of practical results. JOSEPH L. AET, Secretary.

At a recent meeting the Medical Society of the District of Columbia adopted resolutions condemning the advertisement and use of "patent medicines" and commending the *Ladies' Home Journal* and *Collier's Weekly* for the work they have done in exposing these preparations.

Against Antikamnia.

The Saratoga Springs Medical Society, at its meeting held November 17, adopted the following resolution:

Resolved, That we as a society discontinue absolutely the use of antikamnia and all similar preparations and use our influence against their use.

The Proprietary Association Wants Its Members to be Good.

The Proprietary Association is trying to stem the tide. At a meeting held on December 4 a resolution was adopted "advising its members not to use so much alcohol in their patent medicines," and another against the use of cocaine and narcotics. Here is one resolution that is worth quoting in full:

Resolved, That this association urges on its members the most careful scrutiny of the character of their advertising and of claims for the efficacy of their various prescriptions, avoiding all over-statements.

This sounds interesting. Fancy the exploiters of peruna, liqozone, Duffy's pure malt whiskey, etc., etc., etc., avoiding all over-statements in regard to the efficacy of their preparations!

THE STRENUVA VACUUM FRAUD.

Fraud Order Issued by Postoffice Against the Strenva Vacuum Treatment.

The following is a summary of the postoffice investigations and conclusions in a recent case, showing the kind of work being done by that department:

MEMORANDUM IN RE THE STRENUVA COMPANY AND W. OTTIGNON, ST. LOUIS, DETROIT AND BOSTON.

WASHINGTON, D. C., Dec. 16, 1905.

To the Postmaster General:

On June 15, 1905, these parties were duly cited to appear before this office and show cause why a fraud order should not be issued against them for the alleged conduct through the mails of a scheme or device to defraud. June 27 was set as the date for the hearing. At the time designated, and also at subsequent times, to-wit: July 27, August 15 and September 5, the company has appeared before this office through its proprietor, W. Ottignon, and attorney, Mr. Clarkson, with Knight & Brothers of McGill Building, this city. At these various hearings the company has been heard at length in its behalf, and a careful consideration has been given all the matters presented by the company.

The business of this concern consists in the selling through the mails of a so-called "vacuum appliance" for the development and cure of diseases of the male sexual organs. Purchasers are secured through advertisements inserted in newspapers throughout the country and also by circular letters mailed to various persons. Orders are sent through the mails and remittances for the appliance sent in the same manner. I find, after considering carefully all of the evidence adduced in this case, that the pretenses and representations on which the device of this company is sold are false and fraudulent, and that the business of said company is a scheme or device for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises.

1. It is pretended that this appliance will cure conditions in men commonly known as night emissions and daily losses, varicocele, stricture, gleet, impotency or lost manhood, inflammation of the prostate gland, prematureness, nervousness and rheumatism. It is also represented that the appliance will restore full vigor to shrunken and undeveloped organs. (See booklet of company styled "Strenva Vacuum Treatment" and other advertising literature herewith.) I find that these representations are false and fraudulent, and that in truth the use of this instrument will not cure the conditions above indicated as represented.

This device was submitted by Inspector McAfee, who investigated this case, to the St. Louis Medical Society of Missouri, which referred the matter to its committee on public health and legislation, composed of Drs. George Hondu, John Young Brown and Henry J. Scherck. These doctors examined the instrument and the literature of the company setting forth the claims made for it, and reported to their society that, in their opinion, the device was a fraud, and that it was worthless for the medicinal treatment of the conditions for which it is advertised to be a cure. The statements of these physicians are in evidence in this case.

This device, with the advertising literature of the company, was also submitted by this department to the Treasury Department for reference to the surgeon general of the Public Health and Marine Hospital Service for his opinion as to the therapeutic value of the instrument in the treatment of the conditions for which it is sold. The surgeon general states that "the apparatus and method advertised by the Strenva Company are without efficacy for the purpose intended, and that the method is not free from danger." The statement of the surgeon general is in evidence in this case.

Similar instruments sold under similar representations by the Van Best Company of Denver were submitted by the inspector in charge of that division to S. D. Van Meter, M.D., chairman of the Colorado State Board of Public Health and Legislation; secretary-treasurer of the Colorado State Board of Medical Examiners, and president of the staff and visiting surgeon of the Mercy Hospital of Denver, for an opinion as to the value of such an instrument in the treating of such conditions. Dr. Van Meter gave it as his opinion that the device is wholly a fraud and wholly worthless so far as the curing of the conditions for which it is intended to be used is concerned. Dr. Van Meter's statement is in evidence in the Van Best case. Inspector-in-Charge McKee, in his report in the Van Best case, also states that in that case Dr. J. N. Hall and Dr. H. R. McGraw, both of whom, he states, are noted physicians and surgeons of Denver, expressed the same opinion as given by Dr. Van Meter.

The Strenva Company has been given the fullest opportunities to submit evidence that this instrument will cure the conditions for which it is represented to be a cure in the booklet and other advertising literature of the company. The company has totally failed to submit satisfactory evidence, either by statements of physicians or otherwise, that this appliance will cure these conditions as pretended. I am, therefore, thoroughly satisfied from this evidence and the failure of the company to produce evidence of a satisfactory nature showing that this instrument is of value for curing these conditions, that the device is a fraud and that the pretenses and representations made by the company to promote its sale through the mails are false and fraudulent, and so find.

2. It is represented that the use of this appliance is approved by the medical profession and is indorsed and recommended by eminent scientific authorities. (See pages 5, 6 and 7 of the booklet of the company.) I find that this representation is wholly false, and that the use of this appliance is not approved nor recommended by the medical profession for the cure of conditions for which it is intended to be used by this concern.

Particular attention is in this connection directed to the indorsement printed in the company's booklet on pages 6 and 7, purporting to be the indorsement of the *American Journal of Health* of this instrument. It appears by satisfactory proof and is admitted by the company to be true that this *American Journal of Health* is not a medical journal of good standing, and that it is simply a fraudulent publication, printed to sell paid advertisements to various medical concerns doing a mail order business, and to be then used by such concerns as an indorsement of a medical publication. Mr. Ottignon's only defense to this charge when it was presented to him was that he had merely copied that statement out of the booklet of some other concern that was selling a similar device in a similar manner through the mails and which business he had purchased. Even this defense shows the fraudulency of the indorsement for the reason that, while the indorsement pretends to be the indorsement of the instrument of the Strenva Company, it is, according to Mr. Ottignon, not in relation to such instrument, but in relation to the instrument of some other company. The effect of the use of this pretended indorsement of the *American Journal of Health* on the minds of the class of people in whose hands such literature falls and who are uninformed of medical journals of standing is decidedly misleading and deceptive, and is a deliberate fraud.

The company has also failed to submit any evidence to prove that its instrument is indorsed by the medical profession, although the fullest opportunity has been given it to present such evidence. The reports of the various doctors in evidence in this case, the findings of Inspector McAfee, who investigated it, the truth regarding the *American Journal of Health*, and the failure of the company to submit any evidence on this point satisfies me beyond doubt of the falsity of this representation, and I so find.

3. It is represented that this appliance is the *only* safe, sure and permanent cure for the development of weak and shrunken organs. (See page 8 of booklet.) I find that this representation is wholly false and without foundation in truth. As a matter of fact, this instrument is not only the *only* safe and permanent cure for such conditions, but in truth will not cure them at all. The defense made by the company to this charge was that it was simply such an exaggeration of a puffing nature as is employed in business. This representation is, however, one of fact, which is wholly false.

4. On pages 19 and 20 of the booklet are printed articles under the head "Prematurity a Great Cause of Unhappiness." These articles are probably obscene in their nature, and at least are decidedly objectionable. These articles pretend to depict a diseased and abnormal condition of the male sexual system to the end that the uninformed reader may be frightened into believing that his condition is abnormal and that he is in need of this company's instrument. As a matter of fact, the conditions represented are in no ways abnormal, and their presence is not recognized by the medical profession as diseased conditions, but are recognized as conditions which are present in many, if not the majority, of men of normal health. The purpose of the company in this respect is fraudulently to cause the uninformed reader to believe his normal condition is a diseased one, and in this way induce him to purchase one of the instruments sold by this concern. I therefore find that these representations are false and fraudulent and designed to deceive.

On page 21 of this booklet appears this statement: "We sell all kinds of thin tissue rubber goods at low prices." Inspector Larmour of the Chicago Division wrote test letters to the Detroit office of this concern with reference to those pretended

rubber goods, and, as a result of such test correspondence, obtained evidence showing that the rubber goods referred to are such articles intended for the prevention of conception, etc., as it is made a penal offense by section 3893 of the Revised Statutes to sell through the mails or to give information as to where the same may be obtained. The person in charge of the Detroit office was arrested by the inspector after the securing of such evidence and offered to plead guilty to the indictment, but surrounded the plea with so much mystery as to the knowledge and intent in the matter that the court would not receive the plea and ordered a plea of not guilty entered and the defendant's recognizance taken in the sum of \$500 for trial at the March term of the United States Court at Detroit. Mr. Ottignon stated that since the arrest of Mr. Belknap the paragraph on which he was arrested and indicted had been stricken out of the pamphlet. This fact is given as significant of the intent with which these parties have been using the mails and conducting this scheme.

This case was investigated at St. Louis by Postoffice Inspector R. W. McAfee. Mr. McAfee's report is in the case. Mr. McAfee reports that as the result of his investigation of this scheme he was satisfied that the business of the Strenva Company is fraudulent within the meaning of the postal laws.

I find, after giving this matter the most thorough consideration, and examining with care all the evidence submitted, and relying on the findings of the inspector who investigated this case and the statements of the Medical Society of St. Louis, the surgeon general of the United States, Dr. Van Meter and the other physicians of Denver, and the failure of the company to submit evidence in its behalf of the truth of its representations, that the pretenses and representations made to sell this device are false and fraudulent and that the business of the Strenva Company is a scheme devised for obtaining money through the mails on false and fraudulent pretenses, representations and promises. Not only is the device worthless for the purpose for which it is intended to be used, but its use is also attended with danger to the persons using it. I therefore concur in the recommendation of the inspector that a fraud order be issued against this company, its officers and agents as such, and W. Ottignon, at the company's offices from which the business is operated.

R. P. GOODWIN,
Assistant Attorney General for the Postoffice Department.

As a result of the above report, a fraud order was issued by Postmaster General Cortelyou Dec. 19, 1905.

Correspondence

The Detail Man and the Thoughtless Physician.

TOLEDO, OHIO, Dec. 28, 1905.

To the Editor:—Recently the representative of a wholesale drug house was in my office. The man is, I think, a truthful man. Two years ago he had with him a powder, which he said had been tested by competent physicians and had proved itself an almost unfailing cure for cancer.

About a year later he had with him some tablets which he said were a compound, of which the original powder was the base, and that extensive and scientific tests had proved the tablets to be a sure cure for tuberculosis. He showed a formula with each of these articles, but what they were made of, of course, does not matter. The matter for wonder is that a man with such a layout could make a living soliciting among physicians.

Knowing the man and believing him to be honest, I believe him when he says that he sells large orders of the powder and many thousands of the tablets. I believe him, too, when he says that his house has scores of testimonials from physicians substantiating the claims which his house authorizes him to make for their products.

The man knew nothing about the action of medicines, but from association with the physicians to whom he sold the articles, backed up by the faith which the testimonials on file in the home office gave him, he had come to look on the treatment of tuberculosis as merely the getting of a man outside of a specified number of those tablets every twenty-four hours. He had, in fact, supplied several people with samples, and he thought they were showing marked improvement.

It is very encouraging to note among the men who come around with samples that they do not seem so surprised as

formerly, when the samples are declined; the fact arguing, I think, that physicians generally are doing more thinking along the lines of physiologic action of medicines.

I have myself been a "crank of the crankiest" on the subject of the "proprietarys," and as I have criticised *THE JOURNAL* much, it seems only fair that I should add my mite to the great praise it is receiving for the work it is doing in making plain the distinction between intelligent treatment of disease and the handing out of ready-made treatments.

J. L. TRACY.

Governor Indorses Dr. Souchon.

NEW ORLEANS, Dec. 23, 1905.

To the Editor:—I enclose a copy of the letter written me by Governor Blanchard of Louisiana in connection with his acceptance of my resignation. The letter speaks for itself.

EDMOND SOUCHON, M.D.

NEW ORLEANS, Dec. 23, 1905.

Dr. Edmond Souchon, City.

My Dear Doctor:—Several weeks ago you tendered to me as governor of the state your resignation, both as president and member of the State Board of Health.

This action on your part, as also that of the other members of the state board was, I am sure, prompted by a desire on your part to avoid all difficulty in the way of a reorganization of the board, and thereby to remove certain embarrassments of the state administration that had grown up out of unfortunate conditions that had arisen.

In accepting your resignation permit me to assure you that I do not share in the belief that you or your board aided or assisted in the suppression and keeping from the public the knowledge of the fact that yellow fever existed in the city of New Orleans during the last summer.

Your long and successful service in the State Board of Health entitles you to the highest respect and consideration at the hands of the people of the state of Louisiana, and, on their behalf, as governor of the state, I tender you thanks, and wish you a prosperous future.

With high esteem, I remain, most sincerely yours,

NEWTON C. BLANCHARD.

Addition of Physicians to Morphin and Liquor.

READING, MASS., Dec. 26, 1905.

To the Editor:—In *THE JOURNAL*, Dec. 23, 1905, in the discussion of Dr. Pressey's paper, page 1944, a statement is made by Dr. Crothers so extreme that it seems to me worthy of some adverse comment in addition to that which it received from the members who criticised it on the spot. He says that from some studies which he made five years ago and which have since been fully confirmed, he is "convinced that at least from 15 to 20 per cent. of physicians in active practice are victims of morphia and spirit taking." And again: "A general study of the habits of physicians in four of the largest cities of the country showed that from 10 to 15 per cent. were drug and spirit takers. In one city a prominent daily paper made inquiries and concluded that at least 15 per cent. of all persons practicing medicine, including all members of all the schools, were spirit and drug takers. In other cities the percentage has been estimated as high as 20. In one city over 11 per cent. of all physicians were known or reputed to be using drugs."

I have no doubt it would be generally admitted that, for very obvious reasons, it is the brain-working classes, professional men and persons of the nervous temperament who are most likely to yield to the temptations of morphia and among them physicians, having in addition a greater knowledge of and familiarity with the drug, are probably most frequently addicted. It is easy to see how a drug which gives prompt relief from distress, the immediate effects of which are obvious to outside observers not as narcotism, but as full mental vigor, which enables a man to keep about his business for a long time undetected, should only too often be resorted to in some emergency by the practitioner to prevent his business from being neglected and broken up.

A physician of the highest moral character, deservedly distinguished among his brethren and beloved by his patients,

once told me that he used to remonstrate with a certain lady addicted to morphia and to alcohol on the folly of her course, and pointed out to her its dangers and wickedness, "and," said he, "the only way I could get strength to go to see her was to take it myself."

Few of us but have seen promising and successful men among our confreres prematurely lost to themselves and to the world from this drug, but notwithstanding my full share of such experience I have no doubt that Dr. Crothers' figures are very greatly exaggerated, certainly as regards morphia. If, however, we accept his additions of "spirits" and "drugs," the question becomes one of definition instead of statistics. It seems almost ludicrous, in these times of absurd statements from doubtless well meaning but unbalanced ultraists in the temperance reform, that any one should take seriously any estimate of what physicians in any city were "reputed" to be doing in the way of drugs. It depends entirely on where we draw the line, that is, on the personal views of the maker of the statistics, whether we shall find 2 or 10 or 20 per cent. of physicians who deserve to be put in the same class with morphia habitués. It is certainly doing the man who takes an occasional glass of wine or beer in a friendly way a great injustice to do so. There are probably much more than 20 per cent. of physicians who have not thought it necessary for their salvation to become total abstainers, who would be greatly surprised to hear themselves described as "victims" to spirit taking—and their friends would be quite as much so.

Although it is no doubt true that persons addicted to one drug not infrequently resort to some other, perhaps to help them out, as they vainly hope, yet the lumping together of all the persons who may use these two chief narcotics, so different not only in their mode of action, but in their noticeable effect on the character and behavior, a very small percentage perhaps so firmly bound to the one as to be almost irreclaimable without assistance and a great majority using the other as an indulgence, is wholly illogical and entirely destroys the value of even approximate statistics.

ROBERT T. EDDES.

Fees for Life Insurance Examinations.

ASTORIA, ORE., Dec. 19, 1905.

To the Editor:—Referring to the short article in *THE JOURNAL*, December 16, page 1891, in relation to "Fees for Life Insurance Examinations," signed by J. Newton Hunsberger, permit me to say that the Clatsop County Medical Society, of Astoria, Clatsop County, Oregon, took action in this matter at its regular meeting, Oct. 5, 1905, in the adoption of the following resolution:

"Resolved, That, after this date, the fee for medical examination of applicants for Life Insurance, to be charged by members of the Clatsop County Medical Society shall be uniform, and in no case less than five dollars."

The companies affected by this resolution have been notified of the action and have replied in the tone stated by Dr. Hunsberger; but in this particular case they will find themselves "reckoning without their host," for every resident physician of Clatsop County is a member of the Clatsop County Medical Society, and it will hardly be practicable for the company to send an examiner with every solicitor wishing to do business here. Dr. Hunsberger is right in saying that medical societies should take the matter up, and I am sending this communication to you to point the way in which one society has already done so.

JAY TUTTLE.

Physician and the Pharmacopœia.

HILLSBORO, OHIO, Dec. 7, 1905.

To the Editor:—I am reading with pleasure and profit your special articles on the Physician and the Pharmacopœia. I think this a most excellent step in the right direction. Physicians need to be educated along therapeutic lines from the time they leave their colleges until they are dead. Therapeutics among the mass of general practitioners is the mainstay of medicine. There never was such a need as now. Every other department of medicine has made advances in the past ten or fifteen years. *THE JOURNAL* of the American Medical Association should be the leader and the court of last resort in matters of this kind.

J. C. LARKIN, M.D.

Miscellany

Care of the Insane in Brazil.—The October number of the *Revista Med.-Chir. do Brazil* is a special number, profusely illustrated, describing the institutions and methods of caring for the insane in Brazil. The text is in French and is from the pen of J. Chardinal, who quotes as his motto a saying of Prof. J. Moreira, the present director of the national insane asylum: "The civilization of a people is judged by the way it cares for its insane. The national asylum for the insane was founded at Rio de Janeiro in 1852. It is said to be a model institution, and had 1,591 inmates during 1904. Various diagrams are given to show the different forms of mental diseases observed, the causes of death, etc. A number of the states have special insane asylums, S. Paulo's dating from 1852.

The Effect of the X-Rays on the Blood.—E. Bibergeil, Berlin (*Wiener klin. Therap. Wochsft.*, No. 22), has sought to determine whether the action of the x-rays in reducing the number of the leucocytes is exercised directly on the blood elements or on the blood-forming organs. Following the method used by Rosin and himself, based on the fact that the quickness of the action of toxic coloring substances on the blood depends on the resistance of the blood cells, as well as the toxic power of the agent, he took two samples of blood from a healthy individual and submitted them both to the action of a concentrated watery solution of toluidin blue. One of these samples was submitted to the rays, the other not, but no difference as regards the quickness of the color reaction was observed. The same result followed the use of blood from a patient suffering from a blood disease, the rays appeared to have no influence whatever on the coloration or the blood cells. Hence, he considers the view of Heineke that the changes observed in the circulating blood are due, not to a lesion of the blood itself, but to one of the blood-forming organs.

The Eye Symptoms of General Paresis.—A. Joffroy (*Archives de Neurologie*, 1904), has examined the eye conditions in 227 paresies and found anomalies in 212. He considers this figure too small, as some of the cases were examined only once, and he thinks they are liable to appear later in the 15 in whom he failed to observe them. In 144 there was pupillary inequality, complete double mydriasis and extreme double myosis in 29 cases. Very frequently the pupillary orifice does not retain its normal form. In the last 125 examined this was observed 93 times in both pupils and 8 times in only one. He thinks this is, to some extent, a precursor or equivalent of Argyll-Robertson pupil. Of the two reflexes, luminous and accommodative, the former is by far most frequently affected. Its loss with the persistence of the accommodation constitutes the well-known Argyll-Robertson sign. The luminous reflex was found impaired or abolished 171 times in the 227 cases. It was lost on both sides in 103, lost on one side and weakened on the other 14 times, weakened on both sides 35 times, lost on one side and normal on the other 9 times, weakened on one side and normal on the other 10 times. The progressive weakness of this luminous reflex is generally the rule, and the Argyll-Robertson pupil once established is generally permanent, except perhaps during remissions. The accommodation reflex was found impaired or lost only 56 times. It was lost on both sides in 17, weakened on both sides in 13, lost on one side and weakened on the other in 5, lost on one side and normal in the other in 8. In only 2 cases did he find it impaired with normal luminous reflex, and it often remains normal even at a late stage of the disease. The external muscles of the eyes were affected in 38 cases. In 12 there was a simple ptosis, in 14 there were paralyzes or pareses of the other muscles innervated by the third pair of nerves. In 5 there was paralysis of the fourth pair, nystagmus in 5, and in 2 spasmodic contraction of the orbicularis. In only 27 of the 227 were alterations of the fundus observed, papillary atrophy in 22, choroiditis (specific) in 2, old iridochoroiditis in 1, and traces of old optic neuritis in 2. The optic symptoms in paresis he considers of themselves insufficient for diagnosis. His figures are decidedly in contrast as regards fundus conditions with those reported by M. M. Kereval and Dugan (61 per cent. of cases) in the *Archives de Neurologie* in March, 1901.

Marriages

L. L. FLOYD, M.D., to Miss Rosie F. Norman, at Baltimore, December 19.

J. T. MCINTYRE, M.D., to Miss Magilee Pile, at Bristol, Va., December 20.

WILLIAM N. SENN, M.D., to Miss Marjorie L. Lynch, both of Chicago, January 3.

EDWARD B. CLAXTON, M.D., to Miss Irene Robertson, at Nanticoke, Md., December 27.

WILLIAM R. ROGERS, M.D., to Miss Natalie Haynes, both of Bristol, Va., December 20.

JESSE L. COONTZ, M.D., to Miss Hattie Alice Still, both of Woodland, Iowa, December 24.

FREDERICK W. FOCITMAN, M.D., to Miss Leonora Ellen May, at Cumberland, Md., December 27.

H. COLLES GRANT, M.D., Round Hill, Va., to Miss Elinor C. Rowe, at Richmond, Va., December 15.

GUY HARRISON MCFALL, M.D., Detroit, Mich., to Miss Linnie Belle Tucker of Louisville, Ky., January 3.

FLETCHER J. WRIGHT, M.D., Fork Union, Va., to Miss Clara Edna Smith, at Ridgely, Md., December 27.

EDWARD W. ROWE, M.D., Wood River, Neb., to Miss Sarah Belle Harper of Randolph, Neb., December 14.

B. CUTES MILLER, M.D., Cumberland, Md., to Mrs. Cornelia G. Finley, at Washington, D. C., December 23.

GEORGE INGLIS MCLEOD, M.D., Ardmore, Pa., to Miss Margaret G. Twigg of Augusta, Ga., December 27.

E. GUY HOPKINS, M.D., Richmond, Va., to Miss Pauline Dudley Gary, at Fredericksburg, Va., December 27.

FRANZ CARL WALDECKER, M.D., Wichita, Kan., to Miss Dora Louisa Bergmann, at Rockville, Md., December 27.

THOMAS MONROE JONES, M.D., Anderson, Ind., to Miss Elizabeth Shields Baker, at Winchester, Va., December 27.

CHARLES WILBUR HOFFMAN, M.D., Henry, W. Va., to Miss Agnes Hamilton Boyd, at Lanaconing, Md., December 25.

Deaths

Charles C. Chittenden, D.D.S. Ohio College of Dental Surgery, 1866; a member of the American Medical Association; president of the Wisconsin State Board of Dental Examiners since its creation in 1885; president of the National Dental Association in 1904; sometime president of the Madison Odontological Society; a veteran of the Civil War; a practitioner of rare ability, died at his home in Madison, December 15, after an illness of several months, aged 63.

George A. McLeod, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia; formerly a resident of the Philadelphia Hospital and surgeon in the federal army during the Civil War, but since 1893 secretary of the state lunacy commission, and at one time a member of the State Board of Charity, died in the Bryn Mawr Hospital, December 18, from pneumonia, aged 68.

Ezra Herbert Wilson, M.D. College of Physicians and Surgeons in the City of New York, 1882; fellow of the Royal Microscopical Society of London; member of the Kings County Medical Society, Brooklyn Pathological Society and the Associated Physicians of Long Island, died at his home in Brooklyn, December 20, aged 48.

Oliver A. Blumenthal, M.D. Syracuse (N. Y.) University College of Medicine, 1893, of Syracuse; member of the National Society for the Prevention of Tuberculosis, Onondaga County Medical Society, and Syracuse Academy of Medicine, died from tuberculosis at Saranac Lake, N. Y., December 21, aged 35.

Edward Drew Phillips, M.D. Medical College of Virginia, Richmond, 1850; a Confederate veteran; for more than half a century a practitioner of Suffolk, Va., died at his home in that city from malignant disease of the throat, after a long illness, aged 74.

David Oldham Lewis, M.D., medical director U. S. Navy, fleet surgeon of the Pacific squadron, died at Honolulu, Hawaii, December 16 from cerebral hemorrhage, aged 54.

Norman B. Sherman, M.D. Albany (N. Y.) Medical College, 1861, died suddenly at his home in Marshall, Mich., from cerebral hemorrhage, aged 63.

John M. Rand, M.D. Dartmouth Medical School, Hanover, N. H., 1859; surgeon of the Twenty-fifth Army Corps in the Civil War; one of the founders and chief surgeons of the Women's and Children's Hospital, Newark, N. J., died at his home in that city, December 19, aged 72.

John H. Sanborn, M.D. Dartmouth Medical School, Hanover, N. H., 1857, surgeon of the Twelfth New Hampshire Volunteer Infantry during the Civil War, died at his home in Franklin Falls, N. H., December 18, from cerebral hemorrhage, after an illness of one month, aged 75.

John Jabez Caldwell, M.D. New York Medical College, New York City, 1859; assistant surgeon during the Civil War; some-time health officer of Brooklyn, and of Baltimore; member of many scientific societies, died at his home in Summit, N. J., December 18, aged 69.

Walter W. Naylor, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1889, a member of the Philadelphia Medical Emergency Corps and police surgeon in the second police district, died at his home in Philadelphia, December 16.

Charles Eppes, M.D. Vanderbilt University Medical Department, Nashville, Tenn., 1882, died December 26, after a year's illness with chronic nephritis, at Tazewell, Tenn., aged 51.

John R. Crapo, M.D. Medical College of Ohio, Cincinnati, 1877, a member of the American Medical Association, died at his home in Terre Haute, Ind., December 19, aged 55.

William C. Armstrong, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1880, died at his home in Wayne, Pa., December 20.

Queries and Minor Notes

HAS TETANUS FOLLOWED QUININ OR MORPHIN HYPODERMICS?

Dr. H. D. Phelan, San Francisco, calls the attention of *Dr. McCampbell* (whose inquiry on the above subject appeared in *THE JOURNAL*, Dec. 9, 1905, page 1817) to the report of investigations by *Dr. G. Vincent*, in the *Annales de l'Institut Pasteur*. An abstract of this appeared in *THE JOURNAL*, May 20, 1905, page 1646. Tetanus has been frequently reported following hypodermic injections of quinin, while it seems never to have been reported following the injection of either cocaine, caffeine, ergotin or ether. *Dr. Phelan* referred to this in the *California Medical Bulletin* and remarked that in spite of thousands of injections of quinin for malaria in the military hospitals, cases of tetanus do not seem to have been reported from the use of quinin hypodermics.

FORMULARIES.

NEWGICH, CONN. — 1905.

To the Editor:—Can you recommend a good formula—one containing only good prescriptions, rather than a conglomeration of all kinds?

CHARLES P. WHITNEY, M.D.

ANSWER.—Pocket formulary of *Dr. J. Quin Thornton*, published by *Lea Brothers & Co.*, Philadelphia, price \$1.50 net; *Saunders Pocket Formulary* published by *W. B. Saunders & Co.*, Philadelphia, price \$2.00 net; *National Formulary*, published by *American Pharmaceutical Association*, price \$1.00. There are many books of formulary on the market, but the above will be found as satisfactory as any.

State Boards of Registration

COMING EXAMINATIONS.

ARKANSAS MEDICAL BOARD, Little Rock, January 9. Secretary, *J. P. Runyan*, Little Rock.

NEW HAMPSHIRE State Board of Medical Examiners, State House, Concord, January 9-10. Secretary, *H. C. Morrison*, Concord.

VERMONT State Board of Medical Registration, Burlington, January 9-11. Secretary, *W. S. Sav.*, Underhill.

WISCONSIN Board of Medical Examiners, Pfister Hotel, Milwaukee, January 9-11. Secretary, *J. V. Stevens*, Jefferson.

SOUTH DAKOTA Board of Medical Examiners, Sioux Falls, January 10-11. Secretary, *H. E. McNutt*, Aberdeen.

DISTRICT OF COLUMBIA Board of Medical Supervisors, Washington, January 11. Secretary, *W. C. Woodward*, Washington.

ILLINOIS State Board of Health, Great Northern Hotel, Chicago, January 18-20. Secretary, *J. A. Egan*, Springfield.

ALABAMA State Boards of Medical Examiners, January 30-February 2. Secretary, *Charles F. Wheelock*, Albany.

CONNECTICUT November Report.—*Dr. Charles A. Tuttle*, secretary of the Connecticut Medical Examining Board, reports the written examination held at New Haven, November 14-15.

The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number examined was 29, of whom 22 passed and 7 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
University of Vermont.....	(1898)	84.7	
Women's Med. Coll., Baltimore.....	(1888)	75.8	
Baltimore Med. Coll.....	(1904)	75.8	
Medical Coll. of Virginia.....	(1903)	75.1	
College of P. and S., New York.....	(1900) 83.1; (1901)	78	
University of Pennsylvania.....	(1903) 86.4; (1904) 84.1; (1905)	84.1	
Georgetown University.....	(1904) 79.6; 80.2		
Jefferson Med. Coll.....	(1889)	83.3	
Johns Hopkins Univ.....	(1904)	80.1	
McGill Univ.....	(1905)	82.6	
Yale.....	(1903) 75.3; (1904) 81, 84.2; (1905) 82.1, 83, 82.6	83.8	
Harvard.....	(1901)	75.2	
Women's Medical College, Philadelphia.....	(1904)	82.3	
FAILED.			
Maryland Med. Coll.....	(1904) 69.2; (1905)	68.6	
Tufts Med. Coll.....	(1905)	70.2	
University of the South.....	(1905)	70.5	
Baltimore University.....	(1900)	62	
Georgetown University.....	(1904) 73.8; (1905)	64.3	

District of Columbia October Report.—*Dr. William C. Woodward*, secretary of the Board of Medical Supervisors of the District of Columbia, reports the written examination held at Washington, D. C., October 1905. The number of subjects examined in was 17; total number of questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 25, of whom 18 passed and 7 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Albany Medical College.....	(1902)	*84.9	
Baltimore Medical College.....	(1905)	86	
George Washington Univ.....	(1905) 74.4, 81.3, 83.2	80.9	
Howard University.....	(1904)	82.8	
University of Pennsylvania.....	(1901)	90.9	
Georgetown University.....	(1904) 81.4, 81.5; (1905) 82.1, 82.3, 80.2	84.7	
Johns Hopkins University.....	(1901)	84.7	
Columbia University.....	(1904) 81.9, 89.7	81.7	
University of Virginia.....	(1902) 82.7; (1904) 79.6	80.5	
Hahnemann Med. Coll., Philadelphia.....	(1901)	86.5	
FAILED.			
Howard University.....	(1905)	74.5

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Dec. 30, 1905:

Isaac, E. A., asst.-surgeon, granted three months' leave of absence for duty.

Church, James R., asst.-surgeon, ordered to report to Washington, D. C., and report in person to the Secretary of War for temporary duty, and on completion thereof will return to Fort Robinson, Neb.

Carroll, James, asst.-surgeon, left Washington, D. C., en route to New Orleans, La., to attend meeting of American Association for the Advancement of Science.

Pingard, Joseph, contract surgeon, arrived at San Francisco from the Philippine Division, and has been ordered to Fort Leavenworth, Kans., for duty.

Wolven, P. Homer, dental surgeon, left Fort McKinley, Me., on leave of absence for fifteen days.

Wadell, Ralph W., dental surgeon, arrived at Fort Mackenzie, Wyo., for duty.

Wing, Franklin P., dental surgeon, left Jefferson Barracks, Mo., and arrived at Fort Riley, Kans., for duty.

Ware, William L., dental surgeon, left Fort Logan, Colo., on leave of absence for two months.

Hallwood, James B., contract surgeon, relieved from duty at Fort Leavenworth, Kans., and ordered to Washington, D. C., for annual duty of contract.

Kennedy, James S., contract surgeon, left Fort Omaha, Neb., on leave of absence for fourteen days.

Lowie, Thomas S., contract surgeon, reported at San Francisco, from leave of absence for transportation to the Philippines Division.

Leeper, John P., contract surgeon, left San Francisco, on leave of absence for two months from the Philippines Division.

Stuckey, Harrison W., contract surgeon, left Fort Snelling, Minn., for temporary duty at Fort Assiniboine, Mont.

Dickenson, Clarence F., contract surgeon, left Fort Logan, Colo., for temporary duty at Fort Wingate, N. Mex.

Adair, George F., contract surgeon, returned from Fort Jay, N. Y., to his proper station, Fort Wadsworth, N. Y.

Brooks, John D., contract surgeon, left Fort Meade, S. D., on leave of absence for thirty days.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending December 30, 1905:

McLannahan, R. K., asst.-surgeon, having been examined by a retiring board and found incapacitated for active service on account

of disability not the result of any incident of the service, is retired from active service on furlough pay from Dec. 19, 1905, under the provisions of Section 1454, Revised Statutes.

Dorsey, B. H., asst.-surgeon, ordered to Altoona, Pa., January 2, for duty with recruiting party No. 4.

Judd, H. W., acting asst.-surgeon, detached from duty with Naval Recruiting Party No. 4, ordered home and granted leave until expiration of appointment as acting assistant-surgeon.

Conner, E. C., acting asst.-surgeon, appointed acting asst.-surgeon from December 21, 1905.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Dec. 27, 1905:

Grubbs, S. B., P. A. surgeon, granted seven days' leave of absence from Dec. 22, 1905, under Paragraph 191 of the Regulations.

Foster, M. H., P. A. surgeon, relieved from duty at San Diego, Cal., and temporary duty at Galveston, Texas, and directed to proceed to San Juan, P. R., assuming the duties of chief quarantine officer.

Francis, Edward, P. A. surgeon, granted leave of absence for one month from January 17.

Lloyd, B. J., asst.-surgeon, directed to proceed to Guayaquil, Ecuador, and relieve Acting Asst.-Surgeon Luis F. Cornejo-Gomez.

Castle, J. H., chief division of chemistry, hygienic laboratory, granted three days' leave of absence.

Gustetter, A. L., acting asst.-surgeon, excused without pay for a period of twenty-five days from December 21, 1905.

McKay, Malcolm, pharmacist, granted leave of absence from December 13, 1905, to Dec. 31, inclusive.

Walleris, Mathias, pharmacist, relieved from duty at Chicago, and directed to proceed to Memphis, Tenn., reporting to medical officer in command for duty and assignment to quarters.

Herty, P. J., pharmacist, granted seven days' leave of absence from December 18, 1905, under Paragraph 210 of the Regulations.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service during the week ended December 29, 1905:

SMALLPOX—UNITED STATES.

California: Los Angeles, Dec. 9-16, 1 case; San Francisco, 1 case. District of Columbia: Washington, Dec. 8-23, 15 cases, 1 death.

Florida: Jacksonville, Dec. 9-23, 6 cases.

Illinois: Galesburg, Dec. 16-23, 1 case.

Louisiana: New Orleans, Dec. 9-23, 15 cases.

Maryland: Baltimore, Dec. 16-23, 1 case.

Michigan: Grand Rapids, Dec. 16-23, 1 case.

Missouri: St. Louis, Dec. 16-23, 2 cases.

Ohio: Cincinnati, Nov. 3-Dec. 22, 22 cases.

Utah: Five counties, Nov. 1-30, 46 cases.

Wisconsin: Appleton, Dec. 9-16, 1 case; La Crosse, Dec. 16-23, 1 case.

SMALLPOX—INDIA.

Philippine Islands: Manila, Oct. 28-Nov. 4, 2 cases.

SMALLPOX—FOREIGN.

Brazil: Para, Nov. 1-17, 187 cases, 48 deaths; Rio de Janeiro, Nov. 19-26, 7 cases, 3 deaths.

Chile: Iquique, Nov. 11-26, 21 cases, 7 deaths.

India: Bombay, Nov. 21-28, 1 death; Calcutta, Nov. 11-18, 1 death; Madras, Dec. 18-24, 12 deaths.

Italy: City of Rome, Dec. 1-9, 1 case, 2 deaths.

Russia: Odessa, Nov. 18-Dec. 2, 28 cases, 5 deaths.

Urbah: Barcelona, Dec. 1-10, 6 deaths.

YELLOW FEVER—UNITED STATES.

Texas: Galveston, Dec. 24, 1 case (imported from Havana).

YELLOW FEVER—FOREIGN.

Brazil: Para, Nov. 1-17, 39 cases, 9 deaths; Rio de Janeiro, Nov. 19-26, 2 cases, 2 deaths.

Cuba: Havana, Dec. 18-24, 8 cases, 3 deaths; Matanzas Province, Dec. 22, 1 case.

Ecuador: Guayaquil, Dec. 20, epidemic.

Honduras: Puerto Cortez, Nov. 27, 2 cases, 1 death; San Pedro, 6 cases.

Mexico: Coahuacalcoles, Dec. 3-9, 1 case, 1 death; Cordoba, Dec. 3-16, 3 cases, 3 deaths; Orizaba, Dec. 9-16, 1 case; Zimapa, Dec. 3-9, 1 case, 1 death.

CHOLERA—INDIA.

Philippines: Manila, Oct. 28-Nov. 11, 15 cases, 15 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Nov. 11-18, 14 deaths; Madras, Nov. 18-24, 3 deaths.

Russia: Vistula Province, Oct. 26-Nov. 22, 32 cases, 22 deaths.

PLAGUE.

Brazil: Rio de Janeiro, Nov. 19-26, 25 cases, 9 deaths.

China: Hongkong, Oct. 28-Nov. 4, 2 cases, 1 death.

India: Bombay, Nov. 21-28, 8 deaths; Calcutta, Nov. 11-18, 17 deaths; Karachi, Nov. 19-26, 6 cases, 5 deaths.

Medical Organization

WHAT CAN THE COUNTY SOCIETY DO?

In most of the counties of the United States there is now at least a skeleton organization, and, while in many instances the society is doing good work, there are yet others that languish for the want of knowing what to do and how to do it. Local needs vary too widely to enable any one series of pro-

grams to fit the wants of all, but from time to time in this column the attempt will be made to give practical replies to the above question.

Each local society is likely to devise some original and profitable method of work, which will be outlined herein in order that others may benefit. The endeavor will be made, too, to present the subjects for discussion and forms of meeting that will be of help to the commonwealth and to the whole profession, as well as to the society itself. The keynote of medical organization is cooperation. Brief outline reports of society accomplishments will be welcomed.

I. RELATIONS TO NEWSPAPERS.

At the present time, when the exposure of the patent-medicine traffic is uncovering the method by which newspapers have been forced to oppose public health legislation, the relation of the profession to the newspapers is a topic of prime importance to every county society. In our commendation of the press for its alliance with the worst of public frauds we must not overlook the fact that the majority of newspapers were banded innocently enough. They needed money, as does every other enterprise, and nothing at first aroused suspicion as to the fraudulent game in which they were led to a partnership. In North Dakota the newspapers, at great financial sacrifice, supported the well-organized profession in its successful campaign for a pure food and drug law. Dr. McCormack reports, from all along the route of his present tour, that a surprisingly large number of local newspapers are throwing off the proprietary association control and are openly and courageously supporting *Collier's*, the *Ladies' Home Journal*, etc., in their efforts to mitigate the terrible evils of the patent-medicine trade. As these papers do this at a very considerable financial cost, they deserve the hearty praise and support of the profession. One enthusiast suggests that in counties where the newspapers are small and struggling the physicians should carry ethical advertising cards in the papers to compensate the publishers for the loss of patent-medicine advertisements.

Every society should be on friendly terms with the newspaper editors in the county. Meetings should be held to which the editors are invited and at which the subjects for discussion should be patent medicines, physicians' advertising, epidemic diseases, sanitation, health officers, the prevention of disease, and topics of local health interest.

In addition to such meetings, each society should have a "Committee on Relations to the Press," whose duty it should be to keep in touch with the editors, explaining to them the profession's attitude on the various problems of mutual interest that arise. Preferably such a committee should in every possible instance include among its members the family physician of the editor. It should be made clear that these committees are not for the purpose of winning the press to the personal advantage of physicians, but purely for the good of the whole community. They should make it clear that they have no personal favors to ask of the press, but that their function is to see that the papers are enlightened on all the public relations of scientific medicine.

(To be continued.)

THE STATUS OF ORGANIZATION WORK IN CALIFORNIA.

By J. N. McCormack, M.D.

Chairman of the Committee on Organization of the American Medical Association.

BOWLING GREEN, KY.

While it is now very generally known that my work is entirely in the interest of county and state organizations and is done wholly at the expense of the American Medical Association, and although the profession everywhere has been more enthusiastic after my visits than the merits of what was done seemed to warrant, it is not so well known that I have had almost literally to beg my way into most states and that I am still kept out of others where the need for somebody to do something to arouse and help the profession is even more evident. Fortunately, I have been relieved of all embarrassment in the matter by the knowledge that the obstacles or objections are in no way personal to myself, to what I represent or to the association. Most frequently the trouble is that the

council and other state society officials labor under the delusion that their organizations are already so advanced that only the element of time is needed to make them complete. Often I am told that "You could use no argument and bring no influence to bear which we have not already exhausted, and we cannot think that the results would pay for the trouble to us and the expense to the association which would be involved." Back of all these expressed difficulties is the fact that these officials are busy practitioners who are so occupied with their own affairs that they cannot, or at least do not, give much serious thought to anything else which they can postpone or avoid. Being thus relieved of all personal embarrassment, and knowing from long experience what can be accomplished if the opportunity is given, I have just patiently, kindly and factually persisted in my efforts to secure the necessary co-operation and to get in, and have seldom failed to find that the work was most needed in those states where the need for it was least felt.

California is an excellent illustration of what has just been said. It was the first state to adopt the new plan of organization without advice or assistance from the outside. The increase in membership has been rapid, and societies exist in all but a few sparsely settled counties. Through its ably-edited state journal it is leading in some of the best and most fruitful reform work which is being done in this country. Its secretary and editor, Dr. Jones, in a most altruistic and unselfish way, has given up every other interest and ambition in order to devote his entire time and talents to its work. It has a fair medical law and the standard of examinations is high. The fees for medical men are higher than in almost any other state. This is far more than has been accomplished in most states, more than has been done in my own state in several lines, and a pride in it all is natural and easy to understand. Still, from a careful study of their legislative history, of the dominion and insolence of the quack interests in the state and other unmistakable symptoms, I have become convinced that their attractive-looking organization was largely on the surface, and that the unusual prosperity of their profession was not only fortuitous and insecure, but was endangered by the same influences which have operated so disastrously for years in the eastern and middle states.

When I took up the matter with Dr. Jones he insisted that their organization was complete except in a few sparsely settled outlying counties, and no impression was made when it was urged that far more good could be done, and that there was the greatest need for work in San Francisco, Los Angeles, Sacramento and other centers of population than in the country districts, and that his plans could not be considered even well under way until these centers were thoroughly infected with the modern spirit of professional co-operation. When we met at Portland, after fruitless correspondence, I was not surprised to find that we had been discussing entirely different propositions. Earnest and able worker as he was, and is, he had believed that his profession was organized as soon as a large majority of them were enrolled in the membership, with a good attendance and an interesting program at the annual meetings of the state society, and a strong journal for inter-communication and instruction. When he realized that, important and necessary as these things are as links in the complete chain proposed under the new system, they are secondary to and almost entirely dependent for real effectiveness on the county societies, and that these, meeting weekly or oftener, should and can be made live local schools for working out all of the complex problems confronting a rapidly evolving profession, including postgraduate work, practical business methods, and for educating and leading public opinion along proper lines as to the reasons for and methods of securing and enforcing medical and health legislation, he was more anxious for the work to be undertaken than I had been, and at the end of the itinerary exacted a promise that I would return next year for at least six weeks' work of the same kind.

As first arranged the itinerary included Sacramento, Oakland, Santa Rosa, San Jose, Monterey, San Luis Obispo, Los Angeles and San Diego. Later Pasadena and Long Beach were added. Dr. Jones attended all of the appointments with me except those at Santa Rosa and San Luis Obispo, and it soon developed that he had made systematic arrangements to secure the fullest possible representation at all of the meetings. At Sacramento, the first meeting, as the attendance was pretty full, and as I had the privilege of meeting many of the members in advance, opportunity was given for a careful study of local conditions. The personnel was markedly high, especially on the social side, but their county society was of the old perfunctory kind and, although at the beautiful and historic capital of the state, where the need for a live interest in

public affairs and for concert of action was so great, they had never even grasped the idea of such an organization or of uniting and wielding the powerful influence of the profession in everything for the promotion of its own and public welfare. For instance, Governor Pardee, a physician, and a member of the county society since his removal to the capital, had been forced to veto an anti-vaccination bill during the last session of the General Assembly, which he believed could have been easily defeated with a little effort by the local profession. Other instances were related where prominent members had failed or declined to explain important measures to legislators who were patrons or personal friends. On the whole, I got the impression that this excellent profession, more than usually harmonious and prosperous, and located at a point of the greatest advantage and importance, was *practically dead to everything not entirely personal*.

My opportunities for framing an opinion were more limited as to San Francisco and Oakland—in many respects one profession. While their societies attempt little except the reading and discussion of papers and the old order of routine work, so far as could be learned, they were somewhat more progressive than the one at Sacramento. No systematic effort had been made to deal with quackery and other similar problems, and the society appeared to be drifting along in the direction of least possible resistance, although made up of a profession able to guide with a master hand if aroused to the importance of doing so. The society at Santa Rosa was new and enthusiastic, that at San Jose solid and conservative, with delightful personal and social relations. Although adjoining one of the great army posts, with every facility and incentive for clinics and scientific work, the society at Monterey was weak and dormant, and things were not materially different at San Luis Obispo.

We had more time again at Los Angeles and looked into local conditions carefully. Owing largely to the personal efforts of an active and capable president, Dr. Joseph M. King, this society had made a rapid growth during the past year in both membership and interest, and a successful warfare had been waged against a number of unlicensed quacks of the lower order. Their principal work, however, had been along the old routine lines, and no serious discussion ever had been had of the vast practical problems confronting the profession at every turn. They were fairly harmonious and very prosperous and had not been alarmed by the rapid gains being made by the old as well as the almost endless new forms of quackery. And Los Angeles is a veritable paradise for quacks. Chiropractics, neuropsychics, vitopaths, neuropaths, and others not classified, in addition to the common varieties with which we are all so familiar, were extensively and expensively exploited in open defiance of law and decency, all claiming, of course, not to be physicians. These combined interests appeared to have a controlling influence over the public press, and are likely to exercise a like power over the legislatures and courts within the next few years unless all the friends of scientific medicine can be united in an intelligent, systematic, comprehensive opposition. Pasadena has an excellent branch of the Los Angeles County Society, and we organized a similar one with a promising future at Long Beach.

San Diego is entitled to a chapter of its own. In this beautiful, semi-tropical city, so favored by nature and human enterprise, the profession had been engaged in an internecine, personal and factional war for years, which had brought it into great public reproach. Some of the leading physicians had been kept out of all society relations in spite of the best efforts of the councilor and others, until the strife had come to be looked on as chronic and almost hopeless. Declining to hear anything of the origin or history of their troubles, and having all the factions present at the meeting, I frankly told them of the disgrace which physicians had brought on themselves in all of the ages by causeless, senseless bickerings, how these things had consumed energies and barred progress, showed them how all had been equally to blame but equally held in public contempt for these conditions, and then, without ever referring to their local affairs, I tried to convince them that harmony and co-operation were more important in ours than in any other vocation, and that there were at least ten reasons in favor of these pleasant and profitable relations where there was but one for discord. In conclusion, I urged that if discussions existed there a general clasp of hands, without apologies or explanations, and an individual resolution to try to do better in the future would settle everything. In less time than it has taken to tell this story there was a general and joyous handshaking going on until it embraced every one who had been in discord, and it was tacitly agreed to take every one into the society and unite in efforts to make it one

of the best in the state. Dr. Jones and I remained over for a day to join in a boat ride down the bay, which the local profession insisted on as a ratification of the era of good feeling on which they were all so rejoiced to enter.

I feel that the foregoing is a very imperfect and restricted description of local society conditions in California. I have described things as I saw them, but am convinced that what I have said gives a very inadequate conception of this great profession as a whole. For they have a great profession. Individually they are strong. Socially they are delightful. They are more prosperous financially than in any other section I have visited. But they are weak just where they need to be strong—in their county societies. In consequence, there has been little cohesion or unity of purpose, there has been no systematic or well-directed effort to secure the co-operation of the press and other educational agencies in creating and guiding public opinion in regard to medical and public health affairs or to concentrate the influence of the profession itself on proper legislation.

A system of local societies, composed of and uniting all of the reputable physicians in each county, meeting at short intervals and alive to, and in touch with, every proper and available power for good in their respective jurisdictions, are the only agencies through which these things can be done. In California better than in almost any other state all of the other machinery is about complete. They have a strong state society and an able and fearlessly-edited journal. It is the only state in the Union, except Alabama, which has a secretary who can devote his entire time to this work. Dr. Jones deserves to have, and to a remarkable degree has, the profession solidly enlisted in his support. Their legislation is in a bad shape. They especially need a blanket provision in their medical law, like the one we have in Kentucky, which requires every one practicing the healing art under systems now in existence, or which may hereafter be discovered, to take a fair and impartial examination. There are many other things to be done, but this should receive early attention. They have little legislative influence at present, and there is danger from adverse efforts from the combined quack interests at the next session of their General Assembly, but with such a professional and such an able and unselfish leader, and with such a system of local societies as I have urged, it can and should be the banner state of the Union in medical organization, including model medical legislation.

Society Proceedings

NORTHEAST BRANCH PHILADELPHIA COUNTY MEDICAL SOCIETY.

Organization Meeting, held at Frankford, Nov. 27, 1905.

DR. ROBERT H. CHASE in the Chair.

Origin of the Branch Idea.

DR. ALBERT M. EATON said that Massachusetts was the first to have the state divided territorially, with a medical society in each district and that Philadelphia was the first city to have this division made. The movement had its birth in June, 1901. Chicago followed this plan later. Dr. Eaton said that in originating this "branch idea" he had been influenced: 1, By the apathetic condition of the Philadelphia County Medical Society; 2, the difficulty of persuading physicians to join it; 3, the fact that the meetings were held at an hour inconvenient to most of its members, and 4, because at that time it was not properly fulfilling the purposes of its charter. Another factor helpful in the development of the "branch idea" was the reorganization of the American Medical Association. At St. Paul appeals were made to increase the membership of state societies by additions to the county societies. It had occurred to Dr. Eaton that if this work could be done over the whole nation the idea could be carried out along the same lines in cities of large population. The success of the plan was shown in the statement that in 1901 the membership of the Philadelphia County Medical Society was between 500 and 600, while in 1905 it numbers almost 1,200. At present there are five branches, with another one to form in the near future.

Development of the Branch Idea.

DR. JAMES M. ANDERS said that the branch idea was copied from the so-called district societies of London, and that the

fortunes and destiny of the movement in this country were largely in the hands of the present generation of physicians. He referred to the adoption by the American Medical Association, at St. Paul, in 1901, of a report on the reorganization of the entire profession of the country. On account of the topographical peculiarities in large cities the plan recommended could only be carried out by the creation of local branch societies. Reference was made to the reorganization of the Chicago Medical Society as a brilliant example of work along the line of the development of the branch idea. No other city in the United States can boast of eleven districts, each with its own branch society. A group of branches properly distributed in Philadelphia, Dr. Anders thought would serve to create and maintain a proper interest in scientific medicine and other questions of vital import to a community of physicians not otherwise possible. No other factor, he thought, is so influential as an uplifting force in the profession of a community as a society organized under the branch idea. He urged the hearty support by all state and county societies, including the branches, of a movement inaugurated by the American Medical Association at its meeting in Portland in the creation of a "Council on Pharmacy and Chemistry." The cure of the nostrum evil, one of the greatest of the age, demands the concerted efforts of national, state and county societies. Finally, he endorsed the method proposed by the American Medical Association to effect an organization including the entire profession of America.

Benefits of the Branch Plan.

DR. JOHN B. ROBERTS said that branches are valuable because they give the opportunity for men to attend meetings who can not afford the time to go to the central body; and, because the branches encourage modest and timid members to take part in discussions, a thing they would not do in the central body, because they are not among their immediate associates. The branch system is also of advantage, because it trains men in parliamentary usage and enables the membership of the society to pick out men for the high offices who show executive ability, honesty and a desire to aid in the organization of the profession.

Organizing the Profession.

DR. A. B. HIRSH said that as organization of the profession throughout the land is in active progress, and that the county society is recognized as the unit, it is the expectation that practically all ethical physicians will become members. He reviewed the character of scientific work presented in the central body and the branches of the Philadelphia County Medical Society, showing that in this work there is offered a sort of postgraduate instruction of the general practitioner. The branches are supported by the general society and have no separate dues, and to some are added, with advantage, the social feature. Some of the advantages received through membership in the county society are receipt of the *Weekly Roster*, a bulletin containing the programs of all medical meetings for the ensuing week; membership in the Medical Society of the State of Pennsylvania; the receipt of the *Pennsylvania Medical Journal*; eligibility to membership in the American Medical Association, and in the Mutual Aid Association, a local association through which financial aid is extended to widows and orphans of members, and to members in distress. Further features of value accruing to members are those of the reports of the scientific meetings of the central body of the county society; the legal defense of members, with the state's attorney-general as counsel; the suppression of abortionists and illegal practitioners; the work of the committee on public policy and legislation of the county society, which committee, in conjunction with similar committees of other county societies, is enabled to act quickly and unitedly to prevent legislation hostile to the interests of the public and the profession. Dr. Hirsh emphasized the fact that the best interests of the profession as a whole as well as the individual practitioner demand that all reputable physicians should be in one strong, well-organized body. The membership is said to number over 1,100, with 800 eligibles remaining to become affiliated.

BOSTON MEDICAL LIBRARY MEETING.

Regular Meeting, held Dec. 6, 1905.

DR. GEORGE H. MONKS in the Chair.

Traumatic Epilepsy.

DR. DUDLEY P. ALLEN, Cleveland, Ohio, read a paper on "Traumatic Defects of the Skull; Their Relation to Epilepsy." His consideration of the subject was chiefly from the point of view of the surgeon. Of 167 soldiers reported to have been treated for head injuries in the Civil War, 23 are now drawing pensions for epilepsy. Of 527 in the Franco-Prussian War, 25 are now suffering from epilepsy. Often the symptoms are less severe, including only periodic attacks of dizziness, headache, etc. In considering these cases the surgeon must consider: 1. Can relief be obtained by operation? 2. At what period had the operation best be done? 3. What class of patients will most probably be benefited by operation? 4. What are the defects of the usual method of operation? 5. What is the best operation? His paper had chiefly to do with some suggestions as to the answer to the last question, but with regard to the others he noted: 1. There is great variation in the results reported. With a three-year limit most surgeons have obtained but few cures—from 2 to 10 per cent. Others reporting immediate relief as cure have attained 80 per cent of cures. 2. All agree that early operation is best, for then permanent destruction of brain tissue is avoided. 3. All injuries to the head should be operated on if it be judged possible that epilepsy may later develop therefrom. Of other later cases best results are obtained from those which have occurred after previous operation, from cases of Jacksonian epilepsy and when there can be found on the skull or scalp evidence of an injury which may have been forgotten entirely. 4. He prefers the method of the bone drill and forceps rather than the trephine. The chief defect seems to be that the surgeon makes no effort to repair the hole. This may be the reason for so many poor results. It is better to restore the normal. 5. For this purpose he has devised a method of using a bone flap. He lays back the scalp and removes bone and connective tissue, all of it, even down to the brain. He divides the dura, if necessary. Then he makes an incision over the thickest nearly portion of the skull and lays bare down to the periosteum. Next he marks out an area the size and shape of the hole already made, and with a chisel scales off the periosteum with chips of bone adherent underneath, laying it in the hole. The scalp is closed up with the exception of a small cigarette drain. In from twenty-four to forty-eight hours the wound is dressed and the drain removed. The second dressing is made in ten or twelve days. Dr. Allen has had seven such cases, three of which he reported to the meeting. All have healed by first intention and have a firm bony covering. One allowed him later to cut down into the new tissue, and it was found to feel and look like bone. Experiments carried out with much difficulty on dogs gave good results. The animals were killed at intervals of two weeks, one month, three months, four months and five months. It was then shown that the graft first fills in around its edges; it remains viable and grows in thickness; at five months the hole is nearly completely filled with new bone, which is quite smooth on the under side, and is covered.

DISCUSSION.

DR. W. N. BALLARD discussed the subject from the point of view of the neurologist. He said that there are few reliable statistics in regard to the possibility of preventing epilepsy by a suitable operation. In all cases of compound fracture of the skull, however, trephining should be done. Of 70 such cases only one was followed by convulsions later, and of 815 cases of epilepsy at the Massachusetts State Epileptic Hospital only 61 had had any head injury which could be assigned as a possible cause. Twenty-two of these were probably due to some other cause, and in 19 the history is deficient. Thus in only 20 cases is the diagnosis of traumatic epilepsy probable. As to United States pensioners, it must be remembered that syphilis is a very common cause of epilepsy and vitiates any such statistics. He urged early operation, thus avoiding the establishment of a habit. Shock will diminish the frequency of epileptic attacks, only to have them recur later.

DR. J. C. WARREN has operated on 11 cases for epilepsy, of which six were for traumatic epilepsy. He reported these cases in some detail, showing a gain in only two of them. He has lately used the osteoplastic resection. In one case the button and the fragments were replaced and united perfectly. He did not believe that the lack of bony covering is necessarily evil.

DR. L. B. LUND showed a boy $9\frac{1}{2}$ years old who, when 4 years old, had a fall, resulting in a depression back of the left ear. Four and one-half years later he began to have convulsions of a general character, which finally became so frequent as to occur once in two weeks. He was operated on last March and a large piece of depressed bone was removed and a cyst underneath was opened. He thinks that the best cases for operation are those where a cyst is formed which can be removed. He would operate on any case of such a horrible disease as epilepsy, if a scar can be found on the head.

DR. E. E. SOUTHWARD said that the pathologist now expected to demonstrate postmortem in a case of epilepsy defects in the fibrillary fibrosis and a gliosis in Ammon's horns. By Weigert's stain the neuroglia fibrils can be differentiated from the nerve tissue, and by Mallory's method they can be differentiated from the connective tissue.

DR. GEORGE L. WALTON believes in operating early and freely if there is a supposed fracture. A blow often causes a fracture or an injury deeper in without apparent damage on the outer tables. He urged giving the patient the benefit of the doubt by an early operation.

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

*Eighteenth Annual Meeting, held in Louisville, Ky., Dec. 12-14, 1905.**(Continued from page 2028.)*

Gallstones in the Cystic Duct.

DR. L. H. DUNNING, Indianapolis, presented a method which he has employed in one case which greatly facilitated the pressing backward into the gall bladder of a stone impacted into the cystic duct. In this case the gallstone was lodged in the cystic duct in front of a small stricture. After making all the efforts he deemed prudent to press the stone backward into the gall bladder without success, he then unsuccessfully attempted to dilate the stricture with the finger-tips and later with forceps. One of his assistants suggested that he thought they could better dilate with the forceps if they could see the stricture. The walls of the gall bladder were elastic. The liver was turned up, so that the gall bladder was near the surface. The opening in the gall bladder through which he had been working was enlarged a little, and then the stone was steadied and held against the stricture by an assistant. The fundus of the gall bladder was pushed forward toward the strictured entrance into the cystic duct. They so far succeeded as to bring the opening in the wall of the gall bladder directly opposite the strictured opening. They then tried to introduce the forceps tips, but failed. Picking up a pair of probe-pointed scissors curved on the flat, the point was gently worked through the fistula and the scissors opened; this did not dilate the opening sufficiently, so the edge of the fistulous ring was snipped tightly in two or three places, when they were able to dilate the fistula so as to permit the easy exit of the stone. The operation was completed in the usual way. A rubber tube was fastened in the gall bladder and that viscus was anchored to the fascia. Before they had finished the operation, a little bile had flowed into the gall bladder. Two or three ounces of bile were discharged from the tube daily; at first it was dark and thick, but gradually approached the normal color and consistency. The patient made an uneventful recovery, and had but little pain or soreness in the gall bladder region. The procedure adopted in this case may be found of service in others, but it is not applicable to cases in which the gall bladder can not be brought near the surface, or where the gall bladder is thickened by inflammatory deposits. In Dr. Dunning's experience in operating on 93 cases of gallstones, there were 10 cases of stone in the cystic duct requiring considerable effort to dislodge them. In 2 of

the cases occurring early in his experience the stones were crushed and portions left behind, subsequently giving so much trouble that cholecystectomy was finally performed.

Common Duct Obstruction.

DR. J. WESLEY LONG, Greensboro, N. C., stated that this condition is many times more serious than gallstones in the gall bladder. He quoted the unpublished statistics of the Mayo clinic, where more gallstone operations have been done than in any other clinic in the world, showing that in simple gallstones in the gall bladder the mortality of operation is less than 0.5 per cent., while the mortality in operations for common duct obstruction ranges from 11.9 per cent. in benign cases to 40 per cent. in malignant cases. These facts emphasize the prophylactic value of operating while the stones are yet in the gall bladder.

Common duct obstruction in practically all cases, Dr. Long says, is due either to stones or to malignant growths caused by the irritating presence of stones. Gallstones may exist in the gall bladder for a long while without producing symptoms, but once in the common duct, not only pronounced symptoms, but many serious complications arise. The mortality in these cases is due to the complications, the cholemia, infection, inflammation, and exhaustion due to hemorrhage at the operation. He emphasizes the fact that common duct obstruction can be treated only by surgical methods. After removal of the obstruction, the first consideration is drainage, since it is imperative to overcome the infection. No operation must be deemed finished until the patency of the opening into the duodenum is assured.

Attention is called to the importance of not removing the gall bladder in the operation of choledochotomy, since stones occasionally reform in the common duct, and in these cases the gall bladder serves for drainage.

Gangrene of the Gall Bladder; Rupture of the Common Duct.

DR. JOSEPH RANSOHOFF, Cincinnati, read a paper on this subject which will appear in THE JOURNAL.

Electrothermic Angiotribe in Abdominal Surgery.

DR. J. WESLEY ROYCE, Washington, D. C., has employed the Downes angiotribe in 203 abdominal and 27 vaginal operations, removal of uterus, appendix, spleen, kidney, parovarian cysts, portions of intestine, etc. In these 230 cases the author has had two cases of hemorrhage subsequent to operation. He can not believe the method of hemostasis employed was responsible in either instance. In both cases he is confident latent mild infection was responsible for the hemorrhage. In no other instance has hemorrhage occurred, and he has the utmost faith in the hemostatic properties of the instrument. The advantages of the electrothermic angiotribe of Downes in pelvic and abdominal surgery seem to be a more reliable hemostasis than by ligation; freedom from hemorrhage during operation; the ease of its application in locations in which the use of ligatures would be very difficult and uncertain; the greater security against dissemination in radical operations for malignant disease; the ability to sterilize unclean areas before suturing, as in intestinal and appendiceal surgery; lessening of the tendency to the formation of postoperative adhesions; the increased speed in operations, such as removal of the uterus, the appendages, or the vermiform appendix, and the greatly lessened amount of pain following operation. The disadvantages are the danger of accidental injury of the bladder, rectum and ureter; the necessity of great precision in its employment, and the special care necessary to keep the paraphernalia in good working condition.

DISCUSSION.

DR. ANDREW J. DOWNES, Philadelphia, stated that for four years he has not used a ligature except in the case of a woman on whom he operated for extrauterine pregnancy, and who was moribund at the time. He has performed intestinal anastomoses and gastroenterostomies with these instruments; other surgeons have removed gall bladders, kidneys, etc., with them as aids. He has done 400 or 500 hysterectomies with them, while other surgeons have performed 70 hysterectomies with them.

DR. CHARLES P. NOBLE, Philadelphia, having used the Downes instruments a number of times in removing the uterus for cancer, considers them a great advantage. After the uterine arteries are tied on each side, when one comes down to the vaginal plexus, which is the most troublesome part of the operation when the ligature is used, the veins are apt to leak and flood the field, requiring a number of ligatures to secure hemostasis around the cut vagina. If these instruments are used the field will be perfectly dry. From the standpoint of recurrence of cancer, the instruments have not been used long enough to give figures as to results, but one can believe from the work of Byrne that much better results can be obtained with the aid of these instruments than with ligatures, etc.

DR. HOWARD A. KELLY, Baltimore, said that while the Downes instruments are practical and useful, he thinks that if surgeons exercise more care as to the character of ligatures they use daily, it will limit the use of the Downes method. Fine silk ligatures control bleeding from large blood vessels and are practically innocuous.

Operation for Large Rectocele.

DR. GEORGE H. NOBLE, Atlanta, Ga., presented the technic of an operation which is intended only for large rectoceles. Small rectoceles can be relieved by the ordinary perineal operations. In large rectocele not infrequently there is more or less tediousness, loss of blood in the denudation, and certain objections to puckering the overstretched and distended tissues together and forcing them into the rectum. Furthermore, there are unsatisfactory results by infecting the strong and resisting rectovaginal septum. This operation is presented for the purpose of overcoming these objections. In the technic it will be observed that the rectocele is actually resected, and that the strong or normal rectovaginal septum above the weak occluding point is drawn down to the level of the levator ani muscle and securely anchored. The steps are: 1. A thorough dilatation of the anus and releasement of the rectum. 2. Denudation of a wide collar, as it were, the ring around the neck of the rectocele, beginning high up in the vagina and extending near to the promontory of the rectocele. It is unnecessary to remove the mucosa over the last point mentioned, as it is cut away in the resection. By proceeding with the denudation from within outward, the veins of the rectovaginal septum are cut through at a high point and secured with compression forceps, and the necessity of repeatedly cutting the same vessels in repairing the wound is avoided. 3. Two fingers are placed on the promontory of the rectocele, carried into the vagina and out through the anus, forcing the rectocele ahead of them, and in this way completely everting it through the anus. It is seized with a pair of forceps at the point where it protrudes and is gradually drawn down step by step until the lax portions are secured and a feeling of tenseness is felt. If, in drawing the anterior rectal wall down, the normal parts of the rectum do not come as low as the levator ani, the rectum should be liberated by dissecting it from the vagina, which will permit of further descent and allow all of the overstretched tissues to project beyond the anus. 4. A light pair of compression forceps is then placed on the neck of the rectocele just external to the anus for the purpose of holding it in position. 5. Two sutures, preferably medium-sized kangaroo tendon, are passed through the unruptured portion of the perineum close to the sphincter ani muscle after the manner Emmet inserts his tension sutures in perineorrhaphy. These two sutures in passing across from side to side should take up the prolapsed portion of the anterior wall of the rectum. When tied they closely approximate and anchor sound or healthy rectum to the levator ani muscle and rectal vessels in the deep pelvic fascia. 6. The vaginal side of the wound is completed by doing a perineorrhaphy. The protruding rectocele is amputated about three-quarters to an inch external to the clamp, and its edges closely sutured with a continuous suture of catgut. The case is then treated as an ordinary perineorrhaphy, except that a wet soft dressing is placed over the protruding stump. The stump retracts within the anus in a week's time and takes care of itself. The author reported 5 cases in which he has done this operation, with very satisfactory results.

Wandering Retroperitoneal Fibroid Tumors of Uterine Origin.

DR. I. S. STONE, Washington, D. C., stated that these tumors must reach the space behind the peritoneum by way of the broad ligament. This route is the only one open and is necessarily followed by every fibroid which escapes into any part of the retroperitoneal space, however remote. After a fibroid becomes well separated from the uterus, it usually remains in the broad ligament indefinitely and will always do so unless other tumors develop in the uterus and are forced to follow directly in the same channel as the one preceding. Single tumors are generally found in the broad ligament and the development of others must occur before the variety under discussion exists. Many subperitoneal tumors are seen and few, indeed, have been noticed where the tumor has lost all connection with the uterus. Such growths can not become parasitic and receive their nutrition from some other source, as does the intraperitoneal wandering or parasitic variety. He has no experience with a single wandering tumor behind the peritoneum which has entirely lost its uterine connections and believes such development an impossibility for the reason mentioned above, that a *vis à tergo* must exist. The movement of these tumors is, therefore, directly opposite to that of the intraperitoneal variety, for the latter must have either movable organs to assist in their progress, or else traction, a result of adhesive contact, must aid in lifting or elevation of them upward in the abdominal cavity.

Dr. Stone reported 2 cases illustrating the variety described. Both of these grew to very large proportions. In the first, the largest tumor was very high in the abdomen, and was entirely separate from all former uterine connection, including its blood supply. The presence of a large wedge-shaped middle portion is sufficient proof of the mode of development. It has forced other growths both upward and downward, acting as a wedge between the two. In the second case the central portion of the specimen is made up of many small tumors which have appeared to force the larger growths in opposite directions, as in the first case. The largest growth was highest, and was completely separated from the uterus and the tumors below, except by a small amount of connective tissue, and its anterior peritoneal cover. The pelvic tumors in both of these cases were firmly impacted, and in the second case it was impossible to release the specimen without injury to deep and unseen vessels which resulted in fatal hemorrhage. The first patient made a fairly satisfactory recovery, and was now able to attend to her duties as housekeeper.

Report of 182 Operations on the Thyroid.

DR. CHARLES H. MAYO, Rochester, Minn., said that surgery of the thyroid is increasing. These operations are as satisfactory as any made, giving relief with brief disability. In 50 years the mortality has fallen from 40 per cent. to less than 3 per cent., Kocher's percentage being 2. Accessory glands, like bronchial cysts, are more often found in the lines of hypoblastic inversion. The lymphatics serve as ducts. Total extirpation is followed by cachexia in from 50 to 70 per cent. of cases. Graves' disease is probably due to an over- or perverted secretion, the glands showing a general or local condition of cell activity. The great majority of enlargements in young people respond to medication. Part of the benefit obtained in the removal of the sympathetic is from cutting the lymph channels draining the thyroid. During the past 17 years the Mayos have operated on 182 thyroids, with 9 deaths. Of these, 57 were cases of well-marked Graves' disease, with 7 deaths in all, and but 1 in the last 23. Of these cases, 50 per cent. made an early recovery; 25 per cent. did so during several months. The remainder were improved, but had occasional relapses of a temporary nature. Among the remaining 125 operations representing cysts, colloids, parenchymatous and 5 malignant tumors, there were but 2 deaths, 1 from pneumonia, the other from tracheal collapse, on the third day following extirpation of a carcinomatous goiter. Cocain was used in 13 cases, but ether anesthesia, preceded by morphia and atropin, was the rule. The head was maintained in the high position. The incision is usually transverse. Parenchymatous enlargements and some colloids were extirpated; cysts and

encapsulated growths were enucleated. Saline solution was freely given after operation.

Diagnosis of Renal Calculus.

DR. GUY LE ROY HUNTER, Baltimore, Md., first considered the various other maladies of the kidney from which nephrolithiasis must be differentiated, and then the diseases of other organs which may mislead the diagnostician. The Roentgen ray and the wax-tipped bougie are considered invaluable aids in the diagnosis of renal calculus, but they both fail at times, and the importance of the urine examination in all suspected kidney cases was emphasized. Several cases were reported.

Aneurism Treated by Suture Inside the Sac.

DR. F. W. PARHAM, New Orleans, reported 2 cases treated after the method of Matas. One was an idiopathic aneurism of the popliteal artery, the other an aneurism of the second and third portions of the left subclavian. The popliteal aneurism was treated by suture, inside the sac, of proximal and distal openings separately, and continuous suture of the groove of the artery intervening. In the subclavian case only the proximal opening was sutured, the distal bleeding being controlled by ligatures. Both patients recovered. The indications for this procedure are: 1. The practicability of laying open and inspecting the interior of the sac. 2. The possibility of applying a constrictor, clamp, or temporary ligature to the proximal side of the tumor. In the second case reported the suture was employed because the proximal ligature failed to stop the bleeding completely.

The operation of suture within the sac is to be preferred to ligature, because, first, every possible bit of artery is saved except that actually forming the sac of the aneurism. Second, the suture accomplishes simple approximation of the intima and does not cut through, as may happen with ligature of an atheromatous artery. Third, all collateral bleeding in the sac is stopped by direct suture of the vessel mouths within the sac, and packing of the sac becomes unnecessary. Fourth, hence there is no disruption of the outside vascular (collateral) connections of the sac wall, already much relieved by the emptying of the sac. The reconstruction of the artery is to be attempted only in certain cases, as in aortic aneurism, where suture of the proximal opening will, like ligature, probably be fatal, and in other aneurisms where from swelling and lymphangitis, as in Morris' case, the danger of gangrene is too great to risk any interference with the nutrient stream. In such case reconstruction of the artery may be preferred for two reasons: 1. Because even a temporary continuance of the main stream will be a great advantage until the subsidence of edema consequent on the evacuation of the sac shall have somewhat relieved stress on the collateral vessels; and, 2. because, as remarked by Matas and shown in Dana's case, it is feasible at a secondary operation to open the sac again and to close the arterial opening. In abdominal aneurisms the method of Matas offers some hope of cure.

Varicosity of the Saphenous Veins, with Resulting Varicose Ulcer.

DR. ROBERT CAROTHERS, Cincinnati, Ohio, mentioned complete excision of the internal saphenous vein as being the most satisfactory operation to be employed. Until the ingenious invention by Charles H. Mayo of two instruments which subcutaneously strip the vein, it was an operation which required a long incision, tedious dissection and considerable time for its performance. Mayo's operation is very quickly and easily done, but it is not without danger from hemorrhage or sepsis. Dr. Carothers has twice performed this operation and the immediate results were satisfactory. The cases are too recent to judge of the ultimate results. They were old cases with large, troublesome ulcers treated by skin grafting. The patients were able to leave the hospital in less than three weeks, wearing an elastic porous bandage for support, and are now, at the end of about eight weeks, at work as housewives. In one case in which there was a troublesome eczema, after an effort of one week to relieve the same, he again followed the advice of Dr. Mayo, sealing the eczematous area with compound tincture of benzoin until the skin had healed.

Early Diagnosis and Radical Cure of Carcinoma of Prostate.

DR. HUGH H. YOUNG, Baltimore, Md., presented conclusions drawn from a study of 40 cases. He said that carcinoma of the prostate is more frequent than is usually supposed, in that it occurs in about 10 per cent. of the cases of prostatic enlargement, as shown also by Albarran. It may begin as an isolated nodule in an otherwise benign hypertrophy, or a prostatic enlargement which has for many years furnished the symptoms and signs of benign hypertrophy may suddenly become malignant. Marked induration, if only on intralobular nodule in one or both lobes of the prostate in men past 50 years of age, should be viewed with suspicion, especially if the cystoscope shows little intravesicular prostatic outgrowth, and pain or tenderness are present. The posterior surface of the prostate should be exposed as for an ordinary prostatectomy, and if the operator is unable to make a positive diagnosis of malignancy, longitudinal incisions should be made on each side of the urethra, as in prostatectomy, and a piece of tissue excised for frozen sections, which can be prepared in about six minutes and examined by the operator at once. If the disease is malignant the incisions may be cauterized and closed and the radical operation performed. Cancer of the prostate remains for a long time within the confines of the lobes, the urethra, bladder, and especially of the posterior capsule of the prostate resting inviolate for a considerable period. Extraprostatic incision nearly always occurs, first, along the ejaculatory ducts into the space immediately above the prostate between the seminal vesicles and the bladder, and beneath the fascia of Denonvilliers. Thence the disease gradually invades the inferior surface of the trigone and the lymphatics leading toward the lateral walls of the pelvis, but involvement of the pelvic glands occurs late, and oftentimes the disease metastasizes into the osseous system without first invading the glands. Cure can be expected only by radical measures, and the routine removal of the seminal vesicles, vasa deferentia, and most of the vesical trigone with the entire prostate, as carried out in 4 cases by the author and fully described by illustrations, is shown to be necessary by the 40 cases, including 8 autopsies and 10 operations. The 4 cases in which the radical operation was done demonstrate its simplicity, effectiveness, and the remarkably satisfactory functional results furnished.

Surgical Treatment of Floating Kidney; Postoperative Results.

DR. FLOYD W. McRAE, Atlanta, Ga., argued for surgical intervention rather than attempted support by bandages or corsets, but urged careful selection of cases for operation, and the recognition of correction of associated pathologic conditions. He called attention to the frequent coincidence of floating kidney and chronic or recurring appendicitis. He described a new muscle-splitting operation, delivery of the kidney, partial decapsulation, the making of a broad quadrilateral suspensory ligament by dissecting forward the fibrous capsule from near the hilum to beyond the convex border of the kidney. A mattress suture is put in each angle of the capsule, near the hilum, from which the suspensory ligament has been dissected, and including the reflected flap from either pole of the kidney. These sutures are passed deeply into the muscles of the back, high up, so as to bring the kidney well into the hollow of the loin and close up to the twelfth rib. The quadrilateral suspensory ligament is next brought up between the separated muscles and held there by two silk-worm-gut sutures passed through all the structures from within out. A cigarette drain is placed between these sutures and the remainder of the wound closed in layers with interrupted catgut sutures. Care is taken to avoid injury to iliohypogastric and ilioinguinal nerves. The operation was illustrated by drawings. Thirty-two cases were reported.

Chronic Endocervicitis; a New Method of Treatment.

DR. DANIEL H. CRAIG, Boston, said that the diagnosis is made to depend on the conditions of contraction or relaxation of the internal os. In the absence of flexion the inflammation is confined to the tissues external to the internal os. If, on the other hand, the internal os is distinguished with difficulty or

not at all, because of its relaxation and wide caliber, the inflammation is above the internal os, which is thus widely dilated to favor free drainage and to guard against back pressure. Treatment by Craig's method should be strictly confined to those cases in which the internal os is distinctly contracted.

Dr. Craig's treatment consists in curetting the cervical canal up to, but not beyond, the internal os, with a specially designed curette after dilatation of the external os with a conical dilator, also specially designed for this purpose. The operation is quickly and easily performed at the office of the gynecologist without the use of anesthesia, except occasionally a few crystals of cocaine at the external os, and without confinement to bed. Pain, when done without cocaine, is about the same as that due to the filling of teeth. Inasmuch as the most rigid aspsis is requisite to render such ambulatory treatment safe, the author does not offer this operation for the use of those not thoroughly familiar with surgical and gynecologic manipulations, but for those who are able to establish and maintain a rigid aspsis.

The preparatory and after-treatment consist of three 1 to 5,000 formalin douches daily for three days before, and for ten days after, the operation, with avoidance of unusual exertion and abstinence from sexual relations. The cure is prompt and complete, only a relatively very few severe cases requiring more than the original curettement. Tubo-ovariitis or other concomitant disease, which may be aggravated or lead to a recurrence, constitutes a contraindication to treatment, except as an immediate preliminary to radical operation. The treatment is not intended as a substitute for tracheoplasty, nor for nitric curettement in cases in which the disease has invaded the corporeal endometrium.

DR. RUFUS B. HALL, Cincinnati, Ohio, reported 2 cases of traumatism of the ureter and pelvis of the kidney, in which the ultimate results were satisfactory.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Pruritus of the Vulva.

Frederick J. McCann, in the *Clinical Journal* (London), states there are many conditions which may be the source of this trouble; the most important of these is, perhaps, eczema. The lack of cleanliness is also a frequent cause of this condition. The presence of pediculi is another cause of pruritus, for which condition he recommends the mercurial ointment as the best treatment. Another common condition of which he speaks is the presence of tender spots on one or the other side of the vulva, which can be easily detected by using a probe, when the patient will be able to tell when the affected part is touched. The best treatment for this condition, he believes, is the application of pure carbolic acid or tincture of iodine to the tender spot. Sometimes the cauterization is necessary to relieve this condition. After the use of the caustic, whatever it may be, he recommends the application of a bland ointment to these local areas. McCann mentions crops of small boils as frequent factors in producing pruritus. In other cases the condition of the urine is at fault, there is either the presence of sugar or simple hyperacidity. Consequently, whenever a patient presents herself complaining of pruritus the urine should be examined for sugar and the reaction ascertained. Climacteric glycosuria not infrequently occurs in fat women, and in those of the Jewish race, and these cases are best treated by the administration of opium given in the form of a pill, one to six grains daily. This amount should be increased or diminished according to the condition of the patient and the treatment kept up for a month or two.

In cases of hyperacidity of the urine the internal adminis-

tration of alkalis is recommended along with the local application of the following ointment:

R. Bismuthi carbonatis.....	gr. x	[65]
Unguenti simplici.....	ʒi	30]

M. Sig.: Apply locally.

A good alkaline mixture internally, as recommended by the writer, is composed as follows:

R. Potassii bicarbonatis.....	ʒii	8]
Potassii acetatis.....	ʒiiss	6]
Aque. camphoræ.....	ʒi	30]

M. Sig.: One teaspoonful in water four times a day.

The diet must be properly regulated, and the amount of meat diminished.

Vaginal pruritus, he states, may also be caused by vaginal discharges during and after menstruation. The best treatment under these circumstances is the bismuth ointment applied locally, in order to protect the mucous membrane against the irritating discharge. As an injection a bland liquid is recommended similar to the following:

R. Potassii permanganatis.....	gr. v-x	[30-65]
Aque. desti.....	ʒi	500]

Other causes he mentions are pregnancy and epithelioma; he also speaks of cases in which examination fails to reveal anything wrong. These cases generally occur in neurotic women, and no marked changes in the skin and mucous membrane can be detected.

In the examination of these cases one must be thorough in order to get at the proper seat of the trouble, and it will be found that the most sensitive area in the vulva is at that part where it joins the vagina, where one may find small fissures and tender spots in the vicinity of the ring, together with a degree of inflammation extending into the vaginal canal. Consequently no treatment is of any avail unless it should be applied to the vagina as well as to the vulva, and if the general practitioner will take that into consideration he will find success in these treatments where formerly failure has been the rule.

The author recommends carbolic acid as the best preparation in the local treatment of pruritus. It will always cure this condition, he states, if used in the proper strength. It is a local anesthetic and a strong antiseptic.

According to McCann, one should begin first with a solution of 1 in 40, and if that does not prove to be strong enough, it should be increased to 1 in 20 and, if necessary, to 1 in 10. [When using phenol (carbolic acid), as recommended by this author, the possible untoward effects of the drug must be borne in mind and guarded against, as well as a possible idiosyncrasy on the part of the patient.]

There is one point on which he places special stress in the treatment of these cases, and that is that a cure will never be effected in a bad case of pruritus unless the patient is put to bed. The relief obtained by the horizontal position diminishes the local congestion and necessarily improves the condition of the patient. He states that the proper way to apply carbolic acid is to cut strips of lint and to steep them into a 1 in 20 carbolic acid solution. These strips should be about three inches in length. One inch of the strip should be introduced into the vagina and the remainder spread into the form of a fan between the labia, so as to cover the surfaces as much as possible, and should be left in place over night. He attaches importance to this method of application, and says that the strips should not be applied to the vulva alone, but should extend into the vagina, in order to give complete relief. After applying these medicated strips he advises the application to the vulva of a large pad of antiseptic wool over which boracic acid has been powdered, kept in place by means of a T bandage. After the carbolic acid has been used once or twice locally, and the conditions show improvement, the ointment of bismuth carbonate should then be applied. This ointment should be made up of carbonate of bismuth, lanolin and glycerin, which makes a fairly thick paste and forms a very efficient coating to the mucous membrane and the surrounding skin.

In case there are patients who do not yield to the carbolic acid treatment, which is very unlikely, in the opinion of this author, the following combination is recommended:

R. Spiritus chloroformi.....	ʒi	4]
Olei amygdalæ.....	ʒi	30]

M. Sig.: Apply locally to the affected areas with a camel's hair brush or on a piece of wool or lint.

It must not be forgotten, with this preparation, that the vagina must be reached as well as the vulva, in order to cure the patient.

Hot sitz baths are very useful in combination with the treatment just described, because in many cases there is lack of cleanliness and increased amount of discharge. These sitz baths should be tepid and should contain bicarbonate of soda—half a pound of the bicarbonate of soda to the usual bath. After the bath the local parts should be thoroughly dried, the carbolic acid gauze inserted, and the boracic wool applied. When these are removed in the morning, the parts should be thoroughly cleansed and the ointment applied.

The author mentions several lotions which are of use in these cases, one of the best of which is the following:

R. Sodii bicarbonatis.....	ʒi	4]
Olei menthae piperitæ.....	m. v	[30]
Aque.....	ʒi	500]

M. Ft. lotio. Sig.: Apply locally.

Another good lotion is the liquor carbonis detergens, which acts almost as a specific in some cases, especially when the irritation has been alleviated by the carbolic acid preparation. The author recommends the following combination, with directions for the patient to use at home in order to prevent the return of the pruritus:

R. Liquor carbonis detergens.....		
Plumbi subacetatis, ʒā.....	m. x	[65]
Aque.....	ʒi	30]

M. Ft. lotio. Sig.: Dilute with an equal quantity of warm water and apply locally to the affected part.

[Liquor carbonis detergens is a mixture of coal tar 1 part and tincture of quilloja 6 parts.]

If an ointment is preferred, the following combination may be ordered:

R. Liquor carbonis detergens.....	ʒi	4]
Hydrargyri ammonii chloridi.....	gr. x	[65]
Lanolini.....	ʒi	30]

M. Ft. unguentum. Sig.: Apply locally two or three times daily.

The author mentions in this connection that lanolin is very much better than vaselin as a base for these ointments, as it is more soothing to the irritated parts. He also mentions the fact that ointments are much better than lotions. Another lotion which he recommends is composed as follows:

R. Zinci oxidii.....		
Mucilaginosus tragacanthæ, ʒā.....	ʒi	4]
Aque calis.....	ʒiv	15]
Aquam ad.....	ʒi	30]

M. Ft. lotio. Sig.: Apply locally.

As ointments the following combinations may be serviceable:

R. Pulv. amyli.....		
Zinci oxidii, ʒā.....	ʒi	8]
Lanolini.....	ʒiv	15]

M. Ft. unguentum. Sig.: Apply locally. Or:

R. Unguenti zinci.....	ʒii	60]
Pulv. amyli.....	ʒiv	15]

M. Ft. unguentum. Sig.: Apply locally. Or:

R. Acidi hydrocyanici dil.....	ʒi	4]
Unguenti bismuthi.....	ʒi	30]

M. Ft. unguentum. Sig.: Apply locally.

In some cases a 4 per cent. solution of cocaine is recommended to relieve this intense itching, or a weak continuous current in the so-called neurotic cases may be of service.

In the general treatment, rest and regulation of diet are important.

Another most important precaution is to prevent patients from taking alcohol, which they are liable to do because of the depressing effect that the pruritus has on their system. Local sedatives, such as the bromid of sodium in 20 grain (1.30) doses, three times a day, are advisable in some cases.

If the case should be so unruly that carbolic acid can not cure, the author recommends excising the whole ring of the mucous membrane at this sensitive area.

Medicolegal

Admissibility of Evidence of Intercurrent Disease.

The Supreme Judicial Court of Massachusetts holds, in *Dickinson vs. City of Boston*, that, in an action by an administrator to recover for the conscious suffering of an injured person from the time of her injury to her death, evidence which had a tendency to prove that during this period she was suffering and finally died from an intercurrent disease was admissible. But an attempt for this purpose to elicit on cross-examination from the mother of the deceased, who was a witness for the plaintiff, that other members of her family had died from pulmonary tuberculosis, and hence there was a presumption that her daughter also had died from this disease, well may have been deemed in the discretion of the presiding judge as too remote to be of any probative value, and its exclusion afforded no just ground of exception.

Attendance on Wife or Child Under Bankruptcy Law.

The United States District Court, Eastern District of New York, without attempting to define the limits of the provision in Clause 2 of Section 17a of the Bankruptcy Act, as amended in 1903, excepting from the claims dischargeable under the act for those "for maintenance or support of wife or child," holds, in *re Ostrander*, that it does not apply to medical attendance furnished on express or implied contract of the husband or parent to pay therefor while the recipient is a member of the family, and while there is no breach of duty on the part of the person contracting the debt toward the one receiving the service. It says that it is considered that the words, "for the maintenance or support of wife or child," do not refer to a debt incurred for the services of a physician called by the husband to attend the wife while she is in normal relation to her husband. If so, a person supplying goods for a wife or child, or rendering a service necessary for support or maintenance, at the request of the husband, without delinquency on his part, would be beyond the scope of the bankruptcy act. The grocer, the marketman, clothiers of all descriptions, physicians, dentists, in fact, all who, by service or sale, contribute to the support of the family, and thereby to the support of a wife or child, would have claims not dischargeable under the act. The provision has probable application to cases where the person applying for discharge from his debts had so betrayed his moral and legal duty as a husband or parent that another was justified in providing the maintenance and support denied by the one on whom the law places the primary duty.

Admissibility in Evidence of Photographs of Wounds.

The Supreme Court of Nevada holds, in the homicide case of *State vs. Roberts*, that a photograph of a wound in the back after it had been opened by the knife of a surgeon was properly excluded by the trial judge, because the bullet hole was no longer in the condition caused by the accused. But it finds no error in the admission in evidence of three photographs, one of which showed the face of the deceased in the repose of death in which a witness was able to recognize the features of the man picked up, while the others showed the entrances of the bullets in the arm and leg, and were illustrative and instructive in connection with the testimony of the physician and other witnesses. It says that if their tendency was to give a more vivid realization of the wounds than a verbal description, they were less gresome than an exhibition of the man's injuries to the jury in his real flesh and bone, which would have been permissible, if practicable. They had been taken the day after the man died, and were not especially repulsive, and there was testimony as to their correctness. Some extreme cases were cited where photographs were rejected on the grounds that witnesses had described what they would show, or that they would inflame or prejudice the jury—doctrines that this court is not able to sanction, and which are not supported by the weight of authority. If juries can not be intrusted with the pertinent facts for which litigants and offenders are responsible, however appalling they may be, and with the most accurate, instructive and convincing evidence of

those facts, it is time to abolish the jury system. Photography, engraving and the arts of picture making are important factors in our civilization, and the courts in their search for truth should not be adverse to accepting the benefits they bring. A glimpse at a photograph may give a more definite and correct idea of a building or of a person's features than the most minute and detailed testimony. When photographs are shown to be correct representations, and give a better and clearer understanding of relevant facts, it would seem on reason and principle that their use as evidence should be favored. It is generally held that they need not be taken by a professional photographer, and that any one who knows may testify regarding their correctness.

Scope of Privileged Communications.

The Court of Appeal, Second District, California, says that the plaintiff in the case of *McRae vs. Erickson* and others was injured while working for the defendants in the construction of a railway tunnel. Exception was taken to the exclusion of the testimony of a physician as to a statement made to him by the plaintiff at the defendants' hospital, to which he had been taken for treatment. It was contended that there was nothing in the record to indicate that the witness was acting professionally, or with a view to treating the plaintiff, or that the information was obtained with a view to treatment, and that the information was, in fact, not necessary to enable him to prescribe or act for the patient. But the court thinks that the former point was obviously untenable. It says that the witness was a physician and surgeon, and as such was in charge of the defendants' hospital, and his services were remunerated by assessments on the wages of the men, so that he was, in effect, employed by the plaintiff. He examined the plaintiff as a physician, and the plaintiff knew that he was examining him as such, and the information sought was obtained from the plaintiff at the time he was examining him, or some time during the day. The court below was right in holding that the communication was made to the witness in the course of professional employment.

With regard to the second point, the Court of Appeal says that the court was not informed as to the effect of the statement sought otherwise than by questions from which it could not be very clearly determined what the statement would have been. If it was as indicated by one question, asking if the plaintiff made a statement explaining how the rock fell, and how it hit him, the information sought was apparently of a character necessary to the proper treatment of the patient; but information as to the direction or point whence the rock came, asked for by another question, would seem to have been unnecessary for such purpose, and to this extent, if regard be had to the most obvious sense of the statute, the point raised would seem to have been well taken. But to give to the statute this narrow construction would equally exclude from its application many, if not most, of the answers to questions usually put, and properly and necessarily put, by competent physicians to patients in cases of this kind, in order to enable them to act for their patients. This, the court thinks, would be to defeat the obvious purpose of the act.

Therefore, the court is of the opinion that the view of the court below in this case was correct, and that the intention of the statute is to exclude all statement made by a patient to his physician while attending him in that capacity for the purpose of determining his condition; nor does this construction, the court thinks, do violence to the language of the act liberally construed, which is to be understood as forbidding a physician to be examined "as to any information acquired in attending the patient, the acquisition of which was necessary (or which it was necessary for him to acquire) in order to enable him to prescribe or act for the patient." Of this necessity, from the nature of the case, the physician must commonly be regarded as the sole judge; for it would be obviously unreasonable to require of the patient the exercise of any judgment with reference to the propriety of the questions asked by the physician, except, possibly, in cases where the materiality of the question is obviously apparent.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

December 23.

- 1 Exile and Drugs in the Treatment of Tuberculosis. A. Jacob, New York.
- 2 *One Patient's Experience with a Number of Specialists. G. M. Gould, Philadelphia.
- 3 Diagnosis of Bright's Disease. L. B. Pillsbury, Lincoln, Neb.
- 4 *Effect of Copper Sulphate on the Bacteriologic and Chemical Constituents of Large Bodies of Water. W. R. Stokes and J. B. Thomas, Baltimore.
- 5 Postoperative Nausea and Vomiting. L. E. Holmes, Asheville, N. C.
- 6 *Control of Nasal Hemorrhage. H. J. Mulford, Buffalo, N. Y.

2. One Patient's Experience.—Gould reports a case in which the patient had suffered from profound symptoms, seemingly of intestinal nature, but also from psychic symptoms, such as lapses of consciousness at least closely simulating those of major epilepsy, morbid delusions, etc. His disease was diagnosed by the leading specialists as indigestion, hysteria, neurasthenia, nervous breakdown, or hyperchlorhydria, but all the treatments ordered had no effect in lessening the symptoms. One ophthalmologist reported to the neurologist that nothing was wrong with the patient's eyes, and then tried glasses, which gave no relief. A leading consultant made the diagnosis of eyestrain as the fundamental cause of the trouble, and soon after the anisotropia had been accurately corrected by the third oculist the patient was restored to health.

4. Effect of Copper Sulphate on Bacteriologic and Chemical Constituents of Water.—Stokes and Thomas show from their experiments that a dilution of 1 to 100,000 will destroy about 95 per cent. of the algae in water in 48 hours, but that this dilution is not effective against water bacteria. One to 100,000 and 1 to 1,000,000 will destroy all fermentative bacteria in from 24 to 48 hours, respectively. Since the typhoid bacillus is more vulnerable than the fermentative bacteria, it is assumed that this organism can be destroyed in large bodies of water by these dilutions. The dilution of 1 to 100,000 caused a marked decrease in the total and suspended residue, as well as in the nitrates, albuminoid, ammonia, free ammonia and required oxygen. In one case in which the water contained much fine clay in suspension there was a decrease of about 25 per cent. in the total solids. In fairly impure water the fermentative bacteria were not destroyed, and the assumption concerning the destruction of the typhoid bacillus does not apply to such water.

6. Control of Nasal Hemorrhage.—Mulford's method consists in the subcutaneous injection of adrenal extract into the arterial supply at the nearest accessible point to the bleeding area. The injection may be made directly into the artery supplying the part, or it may be thrown into the tissue closely adjacent to the artery. The ingoing arterial current sweeps the solution directly into the leaking area, all the vessels of the part are constricted, and almost at once the hemorrhage ceases.

7. Neurasthenic States, Caused by Excessive Light.—According to Woodruff, an excess of light may be injurious owing to the underlying law that the effect of the short waves is always destructive and never constructive. The various races have been provided by nature with a degree of cutaneous pigmentation suitable for the average intensity of light in the region in which they are native. The blond, fair-skinned races are indigenous in the comparatively dark, gloomy, northern countries, whereas the inhabitants of tropical and subtropical lati-

tudes are universally brunettes. This principle is so radical that the blonds, in the course of time, tend to become extinct if they migrate to more sunny regions. Woodruff states that the excess of sunlight to which the people of many parts of this country are exposed is distinctly injurious and is a potent cause of neurasthenia. He states that, as a matter of fact, neurasthenia is commoner in blonds than brunettes, is worse in cities than in the country, and is vastly benefited or cured by removal to dark, cloudy climates. The same element is of importance in the treatment of tuberculosis, and excellent results in treating the disease in this country and in Europe are obtained in sanatoria where there is a minimum of sunshine. Woodruff suggests that a uniform system of recording complexions be adopted, for the purpose of gathering statistics, and he has devised a numerical scheme of notation, by using which it will be possible to secure uniformity in the records.

8. Curative Treatment of Pneumonia.—Page enters a strong protest against what he terms the non-curative, not to say killing, treatment of pneumonia, which is the prevailing one and includes drugs and forced feeding plus the mischievous effects of hot poultices on hot lungs. The essential features of his plan consist in the use of cool applications to the chest and abstinence from practically all nourishment except water. In this way, he says, the disease when taken early is frequently aborted, and the normal death rate becomes 5 per cent. for private and hospital cases combined, while in private practice alone it is about 2 per cent. For pneumonia the procedure recommended is as follows: A large towel, coarse linen or cotton, is folded lengthwise in the middle, then folded crosswise in the middle, and one-half the length of this four-ply towel is wrung tightly from ice water, or the coldest water obtainable, and again folded crosswise, so as to give four thicknesses of damp towel next the skin, and the same, dry, outside. The damp folds should be freshened as often as they become at all hot, whether this be in ten, twenty, or thirty minutes. At first, in severe cases, the changes will be necessary as often as every eight or ten minutes, the intervals lengthening more and more as the inflammation subsides, and breathing consequently becomes deeper and easier. When the patient is able to breathe naturally, and the compress no longer becomes hot, and before it is felt to be an uncomfortable treatment, this local cooling should cease. In some cases hot applications are also made to the legs. Page emphasizes the untoward results attending the employment of forced feeding, and points out the great advantages of keeping the patient on a diet of warm water until convalescence is established.

11. Tonsillitis.—Niles urges isolation of the patient, and broken doses of calomel, followed by a saline; or, if the stomach be irritable or the patient objects to the saline, one-fourth to one drop of croton oil in combination with hyoscyamus and a cathartic may be given. Quinin in tonic doses, 2 grains, three times a day, should be given in the majority of cases. Strychnin may be added, if indicated. He has found that acenitin not only controls the fever, but may abort the disease. Sodium salicylate is useful in cases presenting the rheumatic diathesis, and guaiac is serviceable both as a gargle and as a constitutional remedy.

13. Complexions of the Insane.—Woodruff discusses the statistical study of the complexion of the insane conducted by Dr. W. L. Russell, the medical inspector of the New York Commission in Lunacy, which shows the remarkable preponderance of brunettes. He concludes as follows:

Owing to the rapidly increasing data as to the damage done to living tissues by the short rays of light and the ultraviolet, it too intense, it is of vital importance that observations be recorded of the complexions of all the sick, particularly those suffering from nervous affections. It has a very practical prophylactic and therapeutic importance. Such data, to be of the greatest scientific value, should, of course, be compared with statistics of the complexions of the general population, urban and rural, native-born and alien, and also native-born of foreign parentage. This country is very backward in such anthropologic work, and it is high time it were taken up in earnest, particularly in the schools. Too long have we been damazing our blonde patients, particularly the tuberculous, by sending them south when they should be kept north. Only brunette invalids will do well in the south.

14. Arteriovenous Aneurism of Occipital Vessels.—Cushing reports a case of this kind in which the aneurism had existed for seven years and was the result of a fall out of a wagon on the back of the head, the patient sustaining merely a superficial contused wound which healed up promptly. A small pulsating swelling appeared shortly afterward and continued to increase in size until finally there presented itself a soft, visibly pulsating tumor, about 5 cm. in diameter and elevated about 2 cm. above the level of the surrounding scalp. Radiating from this more prominent area were several hugely dilated and pulsating veins. The operation in this case consisted of a ligation of the left external carotid artery, with excision of the aneurismal varix. The result was entirely satisfactory.

15. Ten Years' Experience with Diphtheria Antitoxin.—Billings shows that the mortality rate from diphtheria in New York City in 1889-91 was 37.3 per cent., whereas in 1902-04 it was only 10.8 per cent. The mortality has apparently been reduced over 200 per cent. Very much better results are being obtained at present than during the first few years following the introduction of antitoxin. Of 2,447 cases of diphtheria treated between 1895-1897, 641, or 26 per cent., were laryngeal. Of 4,730 cases treated from 1902-1904, only 628, or 13 per cent., were laryngeal. Billings says that there can be no doubt that this decreased frequency of laryngeal involvement is directly due to early, larger and more frequently repeated doses of antitoxin. Less than 0.5 per cent. of all children immunized contracted the disease.

20. Wandering Gallstones.—Estes discusses this condition and cites an illustrative case. He believes that the sequence of pathologic changes is as follows: 1. The development of the stones or stone in the gall bladder. 2. An after-infection of the interior of the gall bladder. 3. Suppuration and ulceration of the lining of the gall bladder. 4. Coincident adhesions of the gall bladder to the transverse colon, to both omenta, and possibly to the duodenum and mesocolon. 5. Perforation of the gall bladder by extension of the ulceration, with adhesions strong enough to resist the pressure of the escaping contents of the gall bladder. 6. Encysting fibrous sac. 7. Gradual working downward of the abscess and contents.

22. Treatment of Pneumonia.—Kohn urges the administration of drugs by the hypodermic method in pneumonia whenever this is possible. External applications of all kinds he condemns, except a cold compress about the chest for antipyretic purposes. Hydrotherapy which mauls and pulls the patient about, Kohn says, is harmful. He emphasizes the importance of careful management of the diet. Milk, he says, should form the principal article of food; the customary dilution with a carbonated water he does not advise. Any water containing carbonic acid, he says, is to be avoided. Strychnin, administered hypodermically, will strengthen a weak and flagging heart. When further medication is needed, Kohn uses camphor and oil. In pulmonary edema he employs wet cups. He regards the tincture of musk as the most valuable heart stimulant.

24. Cold Irrigations in Gonorrheal Urethritis and Endometritis.—Shattuck reports the results obtained by the use of cold irrigations in 277 cases during a period of five months as compared with the results obtained by the use of warm or hot irrigations in 295 cases during the same period of time. The cases consisted of gonorrheal urethritis, vaginitis and endometritis, with or without complications. The complication which retarded the cure most was chronic metritis. All cases were positive microscopically on beginning treatment and the patients were not discharged cured until examinations were negative both clinically and microscopically. The method of irrigation in women was as follows: Vaginal douches with ordinary douche points, followed by urethral irrigations by means of a rellux silver catheter were given twice daily. Intrauterine or intra-cervical irrigations were given once daily, using a return current metal catheter, except in cases where the uterus was not involved. The treatment was reinforced by vaginal tampons, once a day, of 15 per cent. ichthyol in glycerin, or 5 per cent. carbolic acid and alum in glycerin. The antiseptics which were added to the solution were, at different times, lysol in .5 to .7 per cent. solution, potassium permanganate from 1 to 3,000 to 1 to 2,000, and for intrauterine irrigation, zinc sulphate 2 per cent. solution and potassium permanganate 1 to 2,000. During half of the first period, while warm irrigations were being used, the antiseptic was lysol; during the latter half, potassium permanganate was used. During the period of cold irrigation, potassium permanganate was used almost entirely. The results, in general, obtained while warm irrigations were being used were fair. In cases in which intrauterine irrigations were given, there was, as might be expected, an occasional case of uterine colic.

with bilateral fronto-maxillary sinusitis, all had their antra irrigated more than once. The antrum was, therefore, involved in 51 of the 58 cases. Ethmoiditis was considered to be present when considerable swelling was found in the region of the bulla and posteriorly. In 47 cases the swelling was marked and ethmoiditis considered present. In 26 cases the sphenoid was involved, as determined by irrigating the cavity. In the 17 bilateral frontal cases, both sphenoids were involved in 8, the right sphenoid in 2 and the left in 3, making 13 cases in all. Of the remaining 13 cases complicating the 41 unilateral frontals, the right sphenoid was involved 8 times and the left 5 times. So far as known, only 1 patient among the 55 had a return of the disease, accompanying an attack of the grippé. The average duration of treatment was nine days, the shortest four days. One patient was under observation for two months on account of an associated acute maxillary sinusitis, the frontal sinus discharging for five weeks at least, and possibly a little longer. Coakley says that patients suffering from acute frontal sinusitis should remain indoors and be given such drugs as would ordinarily be used in abating the general infection, as, for example, influenza, of which the sinusitis is but a complication. Opium and morphia are contra-indicated. External applications of moist heat, by cloths wrung out in very hot water, always prove agreeable, giving great relief. Occasionally cold applications in the shape of ice cloths or an ice bag to this region will produce the same results. Cold, however, is not usually so well borne as heat. The internal local treatment employed consisted of the establishment of drainage and irrigation with adrenalin, cocaine and saline solutions. The external operative treatment employed consisted of opening into the frontal sinus through the anterior or inferior wall.

61. **New Operation for Draining Frontal Sinus.**—In performing this operation Ingals first introduces a small silver cannula and washes out the frontal sinus with a 50 per cent. solution of the commercial solution of peroxid of hydrogen, warm, immediately following this with a warm saturated solution of boric acid. He then injects into the sinus, slowly, from five to ten minims of the following solution which trickles down about the cannula and anesthetizes the field of operation:

R. Atropine	gr. 1/10	006
Strophanthini		
Suprarenalin, 55.....	gr. 1.5	012
Olei caryophylli	m. 55	2
Acidi carbol.	gr. x	66
Cocain hydrochl.	55ss	6
Aque dest., ad.....	5i	30

He then introduces his steel pilot, which is no larger than an ordinary probe, and, with the patient in the sitting position, administers chlorid of ethyl for about a minute; this insures complete anesthesia. The handle is removed from the pilot and a hollow burr (which has already had a flexible sheath slipped over it and been attached to the chuck of a dental engine) is slipped over this pilot into the nares and up to the lower end of the naso-frontal canal. Gentle continuous pressure is then made, the electric current is turned on, and within a few seconds the frontal sinus has been entered. Before turning on the power Ingals says that one should note just how much of the proximal end of the burr protrudes from the nostril, otherwise he will not know when it has passed into the sinus and may waste time in the futile effort to make it go farther. One can not recognize the drilling of the bone either by sound or by the feeling of the instrument. As soon as the sinus has been entered the burr is withdrawn and a packer, the end of which has been bent to the same curve as the pilot, is introduced, and through it the frontal sinus is packed and dried by a strip of absorbent gauze an inch in width, which is left long enough to stop any bleeding. The gauze is then withdrawn and a similar strip, saturated with 95 per cent. of carbolic acid or with a 10 to 20 per cent. solution of chlorid of zinc is introduced in the same way and allowed to remain a few minutes. The packer is then withdrawn about an inch to insure thorough cauterization of the whole canal, and this strip is then drawn out, through the packer, so as to avoid cauterizing other parts of the nasal cavity. A gold tube, the upper end of which has been sprung together and covered with a gelatin capsule, is then slipped on

an applicator and passed up the canal until stopped by its lower flaring end. A probe is now pressed up against the end of the tube and the applicator is withdrawn. When the gold tube has been placed in the canal it is crowded off the applicator, as the latter is withdrawn, by pushing the spiral tube upward. Within half a minute the gelatin capsule will dissolve and the end of the tube will have opened out so that it will be retained. The operation is then complete. Ingals gives the patient a small sponge with a bent nozzle, by which the frontal sinus can be washed out or medicated. Little or no attention by the surgeon will be needed afterward.

 68 Psychasthenia: Its Clinical Entity Illustrated by a Case. S. L. Schwab, St. Louis, Mo.

67. **Early Ocular Signs of Paralytic Dementia.** Holden records the ocular conditions of 70 paralytics in an early stage of the disease, showing how far pupillary disturbances may be of value in diagnosis. Each pupil was measured with the pupilometer while the other eye was covered, thus excluding any consensual contraction. The shape of the pupils was perceptibly irregular in 51 patients, or 70 per cent. Inequality of the pupils was found in 32 patients, or 45 per cent. The sensory pupillary reflex was absent in 61 patients, or 87 per cent. The direct light reaction was perceptibly sluggish in one or usually both eyes in 15 patients, or 21 per cent. The direct light reaction was entirely wanting in one or usually both eyes in 20 patients, or 28 per cent. The convergence reaction was sluggish in 6 patients, or 9 per cent., in all of whom the light reaction was sluggish or wanting. The size of the pupils ranged from 1.5 to 5 mm., and in 37 patients, or 55 per cent., one or both pupils were smaller than the average size for the patient's age and refraction. Among the 20 cases in which the light reaction was lost, in 7 cases one or both pupils were 4 mm. or more in diameter, but it is likely that they had been small earlier in the disease. Holden believes that in true, uncomplicated paresis there is early in the disease almost constant absence of the sensory reflex, in half the cases irregularity of the pupils, in nearly half inequality of the pupils, in more than half abnormally small pupils, in a fifth of the cases loss of light reaction, in another fifth marked sluggishness of light reaction, and in a few of those with diminished light reaction a diminution of convergence reaction also.

 72 *New Operation for Tubo-Ovarian Abscess. A. E. Barker, Charleston.

72. **New Operation for Tubo-ovarian Abscess.**—To avoid the danger of rupture of this abscess while it is being dissected out, Baker has devised a method which has enabled him to enucleate six of these abscesses in succession without rupturing any of them. The first step in the operation consists in making a free abdominal incision. The patient being in the Trendelenburg position, the abdominal cavity is carefully walled off with pads. All adhesions are broken up, thus liberating the uterus and abscess from the surrounding viscera. With Bissell's clamp, Baker clamps two or more inches of the broad ligament between the abscess and the side of the pelvis, and with scissors severs as much of the broad ligament as is clamped. This will free and make easy the dissection of the abscess on that side. If necessary, a similar clamp is applied between the uterus and the abscess, including in the bite the Fallopian tube and the broad ligament. After this is severed the abscess can easily be lifted out of Douglas' cul-de-sac without making any undue pressure on the friable walls during the dissection. Baker lays stress on the importance of draining through the vagina if infection should occur before or during the operation, also of putting the patient in a half sitting position to favor drainage and to prevent the infection from ascending to the abdominal cavity.

74. Submucous Cautey.—Kopetzky has devised a submucous cautey which lessens the totality of the mass of redundant tissue, but does not destroy the epithelium, and the resulting band of connective tissue is placed so deep in the turbinate body that no interference with the functioning power of the turbinate is brought about. The blade of the instrument is made of an alloy consisting of about 30 per cent. platinum iridium, a mixture of metals which easily and quickly becomes white hot when the electric current is passed through them, yet having sufficient stability to retain its shape and to permit its introduction into the tissues while cold. The cautey end is $1\frac{1}{4}$ inches long, $\frac{1}{4}$ inch broad, and as thin as it is possible to make it without sacrificing rigidity. The handle is made of metal and fits into any standard cautey handle. The field of operation is cleaned of all secretions, and a 4 per cent. solution of cocaine, or a 10 per cent. solution of B. cocaine is applied over the hypertrophied tissue, followed by an application of a 1 to 1,000 adrenalin solution. It is not necessary to cause a complete depletion of the blood vessels, nor is it required to completely anesthetize the mucous membrane. If the mucous membrane is tightly contracted down to the bone, the introduction of the cautey knife into the tissues presents difficulties. The tip of the instrument being sharp, its introduction into the tissues causes very little sensation, if any at all. When the nostril is prepared, the instrument is introduced (cold) into the redundant tissue, along the septal side of the turbinate bone, backward, under the mucosa, as close to, and following the septal side of the bone as it is possible to go. In those cases in which the redundancy of the hypertrophied tissue is irregular, or in which the condition exists, which in a recent study of pathologic conditions of the mucous membrane of the turbinate, Kopetzky designates as "état mamelonné," the submucous cautey should only be introduced into the circumscribed hypertrophied portion; the septum and the remainder of the turbinate being protected from the action of the protruding blade end by thin pieces of cardboard of a Bernay sponge. The instrument in position, the electric current is allowed to pass for a few seconds only, and the instrument is at once entirely withdrawn from the nose before it cools. A slight bleeding may occur from the point of entrance. Looking into the nostril immediately after the cauterization one should observe a whitening streak, slightly broader than the blade of the instrument, shining through the overlying strata of the mucosa. This disappears in the course of a few hours. A light dressing of cotton, wet with a 1 per cent. solution of a silver preparation, is then applied to the entire turbinate. The reaction following this procedure is very slight. The results obtained have answered all the indications calling for the use of the cautey. Kopetzky has employed this method in one case of localized hypertrophy of the inferior turbinate and in 10 cases of diffuse hypertrophy of the inferior turbinate. Among the latter one patient gave postoperative evidence of hemorrhage which, however, was easily held in check by adrenalin. In none of the cases was the reactionary coryza as marked as when the ordinary cautey is employed, and in no case was there any evidence of scarring or scalding except at the small point of introduction of the instrument. This method of cauterization absolutely does away with any chance wounding of the septal mucous membrane and consequent synechia formations.

 5 Acute Arthritis Deformans. B. Abrahams.

4. Atypical Derangements of Knee Joint.—Barker points out that the physician may meet with atypical as well as with typical cases of "internal derangement" of the knee, and that he must be prepared for them. He also insists that with flexion of the joint, combined with external rotation of the knee, it is possible with a good light to discover which of the varieties is present. He has never been obliged to divide the internal lateral ligament, and holds this practice to be most undesirable, as likely to weaken the joint. Further, his own cases—now very numerous—prove that, whatever variety is met with, it is possible to deal with the case without ever allowing the hand or finger to come in contact with the wound or with any part of the joint surface. He believes this to be most important, and that it is one of the reasons why he has never had any inflammatory trouble in these joints which has injured the patients.

 9 Case of Syringomyelia. A. D. Ketchen.

7. Therapeutic Inoculation of Bacterial Vaccines of Tuberculous Infection.—Wright says: 1. Our first efforts ought to be directed to bringing back the infection to the condition of a purely localized infection. Rest in bed and the adoption of measures for increasing the coagulability of the blood would be the appropriate methods for the achievement of this end. 2. As soon as this first object has been achieved it should be our aim to substitute for the inappropriately adjusted, inappropriately interspaced autoinoculations, which were down the patient without achieving effective immunization, a system of appropriately adjusted and appropriately interspaced inoculations of a tubercle vaccine. 3. Finally, as soon as a satisfactory anti-bacterial pressure has been achieved in the blood, it should be an object of endeavor, by the regulation of the patient's exercises and by attention to his blood pressure and by taking steps where necessary to diminish the coagulability of his blood, to irrigate in a methodical manner all the foci of infection with a lymph rich in bacterial substances.

 16 Smallpox Inoculation in India. G. H. Pink.

10. Microscopic Diagnosis of Tinea Imbricata.—Paranhos' method is as follows: The suspected scale is bathed in essence of wintergreen during five minutes. The procedure is repeated with Roux-mixture, absolute alcohol, and ether in equal parts. The scale is placed in the following solution for ten minutes:

Common ammonia.....	3i	30
Distilled water.....	3iii	100

After dissociation the scale is spread in the ammoniacal solution by means of a little glass rod on a slide, fixing it with heat and coloring it with the infrachromatic mixture, then freezing it for ten minutes, having beforehand washed the preparations with distilled water.

Aniline blue.....	gr. xv	1
Carbonated lithia.....	3ss	15
Distilled water.....	3v	150

These different ingredients are mixed up by shaking the liquid well, then warming it in a water-bath during a quarter of an hour, and keeping it in a bottle with emery cork during three days and in a stove at 37° C. The reaction is corrected to a weak alkalinity with a solution of acetic acid at 5 per 100. The coloration being thus obtained, the slide is washed in running water, dried with filter paper and treated with neutral cedar oil. It is examined with an immersion objective.

11. Eucalyptus Oil in Ankylostomiasis.—The following is the routine method employed by Phillips: About 6 p. m. the patient takes a saline purge and then fasts all night, and the next morning at 7 takes half of the following mixture:

Eucalyptus oil.....	m. xxxix	2½
Chloroform.....	m. lii	3½
Castor oil.....	3x	40

In half an hour's time he takes the other half; he is kept in bed, still fasting, until the bowels act. Should any depression occur after the first half of the mixture is taken, the second half is omitted. In young boys and in feeble, anemic patients the dose is divided into thirds and given at twenty-minute intervals. The dose can be repeated every other day. This effects a considerable saving of time necessary for treatment. As a rule, from three to four liquid stools follow, though sometimes only one. In the first stool there are no worms, and in the first solid stool after the medicine has ceased acting there are also no worms. The worms are expelled alive.

 23 Lymphadenoma (Internal) Treated by the X-Rays. F. J. Clendinning.

19. Cyst of Gartner's Duct.—Nyulasy's patient, a woman aged 27, complained of constant aching pains in the back, tenderness in the left ovarian region, severely painful, scanty menstruation, worse since her marriage, four years before, constipation, and occasional difficulty in urination. On examination the cervix was found lying up under the pubic arch, and the narrow end of a fluctuating tumor was dipping down behind the cervix, and in close contact with it. A distinct fullness in the right iliac fossa could be detected on palpation, but was not obvious on inspection. An incision three inches long was made in the midline below the umbilicus. A part of the cyst was seen lying singly in the right iliac fossa. There was a little ascitic fluid surrounding the growth, and its peritoneal covering had a dark, deeply congested appearance. The Fallopian tube and upper part of the mesosalpinx were quite free from the cyst; the abdominal end of the tube was closed. The ovary lay on the anterior and outer part of the cyst, but was not attached to it anywhere. The cyst extended right across, behind the uterus, to the opposite side, and lay in contact with the left broad ligament, which was wrapped firmly round it. The left Fallopian tube was dilated into a hydrosalpinx as large as the caliber of the small intestine; the corresponding ovary was dilated into a cyst the size of a small mandarin orange, and both were bound down by universal ad-

mesion. The uterus was displaced forward by the main cyst, and had also been pushed over to the left as the growth enlarged. On cautiously passing the fingers behind the tumor, as far as they could safely reach, they dipped right down into the pelvis, where many bands of adhesions were felt crossing in an antero-posterior direction, between the pelvic and tumor walls. The tumor itself was situated between the walls of the mesometrium, and was everywhere densely adherent to it. The tumor, moreover, had lifted up the posterior wall of the peritoneum, and there effected some important attachments. The bladder was free from the cyst, which contained two and a half pints of perfectly clear watery fluid. The collapsed cyst was then removed. Many of the adhesions on the anterior part of the cyst were so dense that they could not be torn through with the fingers, but had to be cut with scissors. The right ureter was flattened out into a broad band, firmly attached to the base of the cyst wall, the peritoneum having been lifted off the ureter by the growing cyst. The ureter was separated from the cyst by the aid of dissecting forceps and scissors. This being accomplished, the enucleation of the rest of the cyst was comparatively easy. Having made sure that there was no bleeding into the pelvis, and feeling convinced that there was nothing septic to be feared, either from the growths or the sponges, instruments and ligatures, it was decided to dispense with drainage altogether, and the wound was, therefore, closed in three layers, and dressed with iodoform gauze and a flannel roller bandage. The patient made an uneventful recovery.

21. **Bacteriology of Puerperal Infection.**—Of 159 cases of puerperal sepsis examined by Lloyd, streptococci were found in 83 cases; staphylococci in 30; pneumococci in 17; gonococci in 21; *Bacillus coli communis* in 22; no organism in 21; long bacilli in 20; diplococci, undifferentiated, in 10, and *Bacillus aerogenes capsulatus* in 2.

23. **Lymphadenoma Treated by the X-Rays.**—On examining his patient Clendinnen found a tumor in the abdomen lying to the right of the umbilicus, extending about 2½ inches upward and downward, and 3 inches to the right. It felt lobulated, was firm, fixed, tender, and it did not move with respiration. It had an apparently communicated impulse. The pulses in the femorals and tibials in both limbs were equal. The abdomen was opened by an incision through the right rectus sheath, the rectus being displaced. The tumor was found to be retro-peritoneal, the posterior peritoneum over it was divided, and the tumor exposed. It consisted of a mass of enlarged lymphatic glands lying along and adherent to the vena cava and aorta. It was considered inadvisable to remove the growths and the incision was closed. The wound healed, and the patient was given an arsenic preparation and array treatments. The tube used was what Clendinnen terms a three-degree tube, situated about 4 inches distant from the tumor, with a current of 3 mp. in the primary. The sittings lasted about ten minutes, three times a week, with the exception of a few intermissions owing to a slight dermatitis. After 27 treatments the tumor had apparently disappeared, and two months later it had totally disappeared.

Fracture from Tearing Out of Tuberosity of Tibia.—Gaudier and Brouet review the 15 cases of complete and the 6 of incomplete tearing out of the anterior tubercle of the tibia on record. They discuss the various features and the prognosis, and emphasize the fact that the restoration to normal of the limb depends on proper treatment. In 17 of the cases, medical treatment alone was attempted, but the fine results obtained in the 5 cases treated by surgical measures convinced them of the necessity of further intervention in this line. The pain of the fracture was relieved at the exact point of the solution of continuity of the bone of incomplete fracture, the swelling of the con-

form of a crescent and the ecchymosis extends far downward on the leg. In case of complete fracture with involvement of the synovial membrane, the local swelling is surmounted by a characteristic swelling suggesting an effusion into the joint. The patella generally slides upward from 4 to 10 cm. and is abnormally movable in all directions. Early massage is important in treatment of the incomplete fracture. Hemarthrosis requires operative treatment. In general, reduction of a complete fracture is easy, but in Gaudier's case a silver wire was passed through the ligamentum patellare in order that the necessary traction could be safely exerted. The fractured portion was nailed in place or sutured with wire or held with a Jaccoud double-pointed nail in the various cases reported. After the suture, the leg was placed in a cast for ten days, after which massage and passive movements were begun. Gaudier's patient was able to walk on the twenty-first day after the operation, which was performed thirteen days after the accident. The perfect results after the broken portion was secured with the double-pointed nail and with a wire suture are shown in a radiogram.

25. **Improved Technic for Gastrostomy and Jejunostomy.**—The simple technic described prevents reflux of fluids injected to feed the patient and also prevents the loss of bile or pancreatic juice. The loop of intestine or the stomach wall is fastened in the wound and the seromuscular coat is fastened to the parietal peritoneum only, with from four to six U-shaped, fine, silk sutures, leaving exposed a patch of the wall of the jejunum not larger than 1 sq. cm. at most. The walls of the abdomen are sutured above, still leaving this patch exposed. A Nélaton sound is then worked into the exposed part and pushed in for from 8 to 10 cm. toward the right. The sound is withdrawn after the nutrient fluid has been injected. The sound should be withdrawn very slowly, and if no more than 200 or 300 c.c. are injected at two-hour intervals there will be no reflux of fluids. In the 2 cases described, the results were eminently satisfactory, as also in a case in which gastrostomy was done by this technic.

27. **Cancer of the Pyloric Antrum.**—Delore and Leriche relate the particulars of 8 cases of juxta-pyloric cancer to call attention to the special features which distinguish a malignant neoplasm in the antrum. In every case in their experience the tumor was hard, like pasteboard, not knobby. The first stage of the development of a cancer of the antrum is characterized by gastric troubles, but vomiting is not observed. In the second stage, the symptoms are those of stenosis of the pylorus. The possibility of a tumor in the antrum should be suggested when a woman in the neighborhood of 50, previously healthy, presents certain vague digestive troubles, a little oppression, pains of variable intensity, a burning sensation, and sometimes acid or watery regurgitations. At the same time the appetite suffers, the patient loses relish for meat and fat food, and she grows thin and weak, although still able to keep about. The symptoms may persist about the same for several months or even years. One of the patients described had been a "dyspeptic" of this kind for thirteen years, but there had never been any vomiting. The lesion was found to be very extensive. Another patient had had watery regurgitations every morning for a year. In another patient this stage lasted only three months. The tumor in this case was evidently unusually virulent, as recurrence was observed seven months after resection of the stomach. Pain is frequent in this variety of cancer, presenting the characteristics of hyperchlorhydria. Tardy hyperchlorhydria should be regarded with suspicion. Watery regurgitation is another suspicious symptom. The end of this stage is signaled by the appearance of a tumor, but it is not definite at first and may escape discovery for a time, during which the patient is usually treated with medical measures until the second phase of the malignant disease announces its onset by vomiting. Cachexia rapidly develops and surgical intervention is then too late to effect a cure. Laparotomy performed during the first stage always revealed more extensive lesions than had been anticipated. Delore's experience has convinced him that cancer of the pyloric antrum is, of all gastric cancers, the most amenable to suitable surgical treatment if this is resorted to in time. Its movability, the distance from the duodenum, its slow evolution, all are condi-

tions which favor gastrectomy. The operation should be extensive, with subtotal ablation of the stomach. Before last only 1 out of the 7 patients on whom he has operated since 1903. Only 1 patient has presented recurrence; a secondary gastroentero-anastomosis was done a year ago, and the patient is still alive. Her condition is evidently much better than if the latter operation had been done at first.

28. **Surgery of the Heart.**—Guilaub summarizes the details of 66 cases of injury of the heart in which a suture was attempted, adding 4 more in which the operation was not concluded. The bullet was not extracted in some of the cases, but causes no disturbances. Experience has shown that it is practicable and important to ligate the coronary vessels when they are found injured. Guilaub has studied on dogs and rabbits the symptoms of various kinds of injuries of the heart and the best technic for treating them, as he relates in detail. Stab wounds bleed the most, and those inflicted during systole more than those in the diastole, and the perpendicular more than the slanting. A wound in the left ventricle stops bleeding sooner than one in the right. Even the smallest wound in the auricles proved fatal for rabbits. The patients recovered in 26 out of the 66 cases recorded, the proportion of patients saved by prompt intervention being thus 39.3 per cent. Twelve of the patients recovered without the slightest complication. The signs in Lisanti's patient alone suggest a possible aneurism in the heart. The extensive monograph concludes by recommending cardiorrhaphy as liable to save the patients from almost certain death while leaving them with a heart nearly as sound and vigorous as it was before the injury.

31 (No. 49.) *La cyanose onctueuse. L. Cheinise. Review of literature. See page 79 of last volume of THE JOURNAL.

29. **Inflammation from Ptois of the Cecum.**—Delbet has had a number of patients who complained of disturbances in the region of the appendix and in whom the trouble proved to be the result of ptosis of the cecum while the appendix was found sound. In 3 cases the appendix had been removed on the assumption of appendicitis, but the disturbances persisted afterward. In others he saved the sound appendix from unnecessary removal and it has never given trouble since. The patients are constipated and there is pain in the iliac fossa, which is both spontaneous and elicited on pressure. The pain is more diffuse than in appendicitis, and it is a little higher and outside of McBurney's point. The trouble is essentially generalized paresis of the intestines, most pronounced in the large intestine. The affection is liable to be extremely painful and requires active treatment. Dieting and enemata may give relief temporarily in some cases, but Delbet has found that all disturbances cease when a fold or tuck is taken in the wall of the cecum, turning the fold inward and thus shortening the long bag made by the sagging gut. The cecum is seized with forceps 1 cm. below the mouth of the small intestine, and another forceps is applied on the opposite side. Slight traction on the forceps flattens out the round bag of the sagging bowel, and the part below the forceps is turned up inside the cecum. The straight, horizontal edges left, just below the two forceps, are sutured across with No. 3 catgut. The results of this operation in a case he describes apparently have been entirely satisfactory.

30. **Sensibility to Pressure, Heat, Etc.**—Marinisco groups in four classes the various disturbances in the sensibility noted in pathologic conditions of the nervous system: 1, alteration in all forms of sensibility; 2, abolition of sensibility to pressure or to the vibration of a tuning fork, or to both, with retention of all other forms of sensibility (this is the type of anesthesia to which von Strümpell and Marinisco have called special attention); 3, abolition of sensibility to pain and to heat, with retention of all other forms of sensibility (the syringomyelic type); 4, changes in the sensibility to heat, to contact and to pain, with retention of the sensibility to pressure and to the tuning fork. He is convinced that these various forms of sen-

sibility are transmitted by different sets of conductors. The sensibility of different planes of the tissues is not identical. Pain is not a special sensibility, but rather a defensive reaction. The nerve fibers conducting the different forms of sensibility probably lie close together and may intermingling, while retaining their relative topography, as he shows by a number of illustrations.

32. **Behavior of Tubercle Bacilli at Entering Point.**—Baumgarten does not believe that we can decide with certainty as to the route followed by the tubercle bacillus in infecting the organism. Only in rare cases of cadaver infection is it possible to trace exactly the mode of entry. In other conditions, study of the localization, size and extent and arrangement of the tuberculous products in the infected human body may render this or that route more probable, but our knowledge is not certain. The lack of positive data imposes the necessity for considering all routes as possible, and consequently adopting prophylactic measures not only against infection from inhalation and from feeding, but also considering congenital transmission and all other possible sources of tuberculous infection.

33. **Pathogenesis of Diphtheria.**—Scheller has made a practice of bacteriologic examination of the mouth and nose of all patients before and after operations on the nose. He has found that diphtheria bacilli can survive longer in the nose than in the throat, and that apparently healthy persons can harbor the bacilli and be a source of infection to others and to themselves if their resisting powers become reduced from any reason. He has often noticed the development of tonsillitis after operations on the nose. Animal experiments confirm these facts. In a recent case, a young woman was to be operated on for the removal of a hypertrophied turbinal, which almost completely obstructed one side of the nose, with resulting headache and a tendency to coryza. As diphtheria bacilli were found in her nose, almost in pure culture, during the five days before the operation, Scheller did not wish to operate, fearing that diphtheria might develop, although he had never heard of an instance of the kind. The young woman was healthy, except for scoliosis, and insisted on the operation without delay. She returned every day for after-treatment, and the third day exhibited the symptoms of typical diphtheria with false membranes in the throat. After an injection of diphtheria antitoxin the symptoms subsided. It was learned afterward that the patient had been exposed to diphtheria three weeks before the operation. The bacilli had evidently lurked in the nose all this time without causing infection. The operation had increased the disposition to the disease, and infection resulted. This experience suggests that in many cases of throat diphtheria the nose may be regarded as the entering point of the bacilli. Various influences, chemical, mechanical, infectious or of other nature, might increase the predisposition, as did the operation in this case, and may start a diphtheria process in a bacilli carrier. The practical lessons from this experience are that persons in the environment of diphtheria patients—who are almost certain to harbor diphtheria bacilli in their nose or throat—should avoid all injurious external influences liable to fan the spark into a blaze. Also that the bacilli should be destroyed by diligent disinfection of the nose and throat, without waiting for them to die off spontaneously.

34. **Action of Radium.**—London has been conducting research with very small amounts of radium, applied for a fraction of a second, to learn the effects of such minimal exposures. He found that the application of 18 mg. of radium, for a quarter of a minute, to the inside of the forearm caused a reddish spot to develop in the course of a few days. The spot grew brown

in time, but shows no signs of subsiding, although two years have since elapsed. In some tests of the action of radium from a distance, he placed 25 mg. radium on top of a cage, 31 cm. high, in which were three rabbits. After two weeks the rabbits' hair fell out, the ears became necrotic, and the spleen, the sexual organs and the nerve elements showed signs of extreme degeneration. The ulcerations on the rabbits' skin always healed over with scar formation. This suggested that connective tissue escaped injury from the action of the radium. This assumption was confirmed by his experience in a case of cancer of the ileocecal valve which had been rendered accessible by a broad opening for an artificial anus, a palliative measure for the inoperable growth. A capsule with 10 mg. of radium bromid was inserted in the artificial anus for twenty-four hours on five occasions during the course of six or seven weeks. The cancer did not seem to be influenced, but the wound over it rapidly healed, the artificial anus closing by the rapid formation of granulation tissue under the influence of the radium.

35. Prevention of Puerperal Fever.—Preiss urges the distribution of circulars to midwives describing the means of avoiding puerperal fever. The midwife must give one of the circulars to each pregnant woman applying to her, and when the birth is reported the official should inquire whether the midwife gave the circular. If not, she should be fined. Preiss gives a suggestion for the contents of such a circular.

37. Fever During Menstruation as Early Sign of Tuberculosis.—Frank announced four years ago that a rise in temperature preceding or during menstruation is a strong presumptive sign of a morbid process somewhere in the body. It points especially to tuberculosis, and if the woman is anemic and thin, with a tendency to sweat and to catch cold readily, the physician will do well to inaugurate antituberculosis treatment or to recommend a sanatorium, superfeeding or a course of cinchamic acid or iron and arsenic. He is convinced that the normal limit of the temperature is 37.5 C. (99.5 F.), measured in the rectum, and that even a fraction of a degree above this is fever. Sabourin and Kraus have also recently pointed out the importance of fever during menstruation as an early sign of tuberculosis. Measured in the rectum, a fraction of a degree above normal may be due to the hyperemia of some inflammatory affection in the adnexa, but, if such can be excluded, then the assumption is in favor of tuberculosis.

53. Diagnosis of Tumors in Suprarenals.—Israel reviews the lessons he has learned from 9 cases of suprarenal tumor. The

differentiation of a tumor under the costal arch is mainly by exclusion. If the kidney, gall bladder and liver can be excluded, a tumor in the suprarenals may be assumed. A tumor in this region may also be suspected when indications of a malignant affection in the kidney or suprarenals are accompanied by paroxysms of pain and paresthesia in the region of the lumbar plexus, although no tumor can be discovered by palpation. Febrile states under these conditions, with exclusion of other causes of fever, are corroborative evidence. He gives illustrations of his cases, classifying them in five groups, principally according to the palpation findings.

45. Saccharoscope.—Citron's instrument is based on the loss of weight during the fermentation of the sugar in the urine. It is said to be reliable, simple and convenient.

47. Permanent Changes in Skin After Radium Exposures.—Telangiectasia is observed at the edges of the cicatricial atrophic skin after radium as after Röntgen exposures. It appears much more tardily, and Schmidt regards it as a new formation of vessels. He exposed eight spots on his own arm to the action of 5 mg. radium bromid, and telangiectasia developed at each point from four to six months later. The exposures were from twenty to ninety minutes long, and the telangiectasia was proportional to the length of the exposure. At two other points exposed for only five minutes there is still a visible pigmentation and the blood vessels are evidently enlarged. This tardy action of the radium rays interferes with their use for vascular nevus, as the final outcome of a white cicatricial surface, striped and spotted with red, is worse than the original nevus. Finsen treatment is far preferable. Forchhammer has thus cured 49 cases, the smaller nevi vanishing completely and the larger ones showing notable improvement.

49. Wind and Drafts.—Wind is air under pressure, and is experienced as agreeable. A draft, on the other hand, is a current of air under lesser tension than the prevailing barometric pressure. The air is being sucked out of the room, and, therefore, it has an aspirating effect, producing suction, which is experienced as disagreeable. It makes one feel colder than when wind of the same temperature is blowing on the body. Herz has noticed that the skin feels a weak outward draft at times as if cold air were blowing inward.

50. Prevention of Vomiting in Tapeworm Cures.—About fifteen minutes before administering the tapeworm remedy Apolant gives one or two 0.3 gm. tablets of equal parts of menthol and saccharum lactis. This reduces the sensitiveness of the stomach without interfering with the action of the tapeworm-expelling drug.

51. Treatment of Functional Psychoses.—Mendel lays great stress on medical oversight of children whose parents are inclined to be "nervous," if the children display the least tendency that way. Especially before puberty is it advisable to remove the child from the home atmosphere to some family in the country or in a small town living a simpler, more wholesome life. Milk, vegetables and fruit should be the principal diet for such children. In a confirmed psychosis, wet packs, baths and massage should be given a thorough trial in case of insomnia before resorting to drugs. When the patient refuses to eat, a glass of milk or bouillon and crackers should always be left on a table beside the patient's bed. He will sometimes be thus tempted to eat when he thinks no one is looking. Patients who soil themselves should be taken at brief intervals to the water closet, and ingestion of fluids should be restricted. Another point which Mendel emphasizes is that nothing should be said in the hearing of patients with mental derangement that would cause annoyance if repeated to others later. The lack of this caution has led to much annoyance in some instances. He regards opium in increasing doses and then tapering off as the main reliance in melancholia, supplemented by rest in bed and a strengthening diet. He gives opium to a maximum of 1 gm., with injections of oil in case it causes constipation, and a few drops of hydrochloric acid after meals.

57. **Prevention of Laryngeal Stenosis After Intubation.**—It has been von Ranke's experience that stenosis of the larynx after secondary tracheotomy after intubation can be prevented by not allowing the larynx to be excluded from the respiration a moment longer than it is absolutely necessary. He thinks that the stenosis is due mainly to the lack of the normal participation in the breathing act.

58. **Treatment of Asthma.**—Avellis remarks that internal medicine has washed its hands of asthma since the Leyden crystals have been found to be a consequence and not the cause of the affection. Rhinologists and neurologists also disclaim responsibility in regard to asthma, and the tuberculosis specialists also turn their backs on it. He hopes that more physicians than has hitherto been the case will make a specialty of this disease. The treatment requires a fundamental knowledge of neurology and of neuropathies in general, also a small sanatorium equipped as for nervous diseases with appliances for hydrotherapy, massage, resistance and breathing exercises and air baths, associated with a rhinologic clinic and inhalatorium; in short, a special institution for treatment of non-bacillary lung affections. It would be well, he thinks, if such sanatoriums could be located at different altitudes, so that there might be an exchange of patients to correspond to the climate found best for individual cases. The first attack of asthma should be the warning signal to institute a regular course of training to ward off future attacks, just as the first hemiplegia is the signal for a course at a sanatorium. Several months should be devoted to a systematic course of training in measures to ward off future attacks. The entire mode of life must be regulated to conform to the rules of hygiene, and the respiratory organs should be strengthened by appropriate gymnastics. The patient must also be taught the various measures which have proved effectual in warding off impending attacks, such as counting at each expiration to divert the mind, voluntary modification of the respiratory rhythm, or stimuli applied to the skin, etc. Such training is especially important for children.

60. **Veneral Statistics Under Unusual Conditions.**—Müller states that the garrison of 24,000 men at Metz is a remarkably high proportion of males to a total population of only 80,000 in the city of Metz. As careful records are kept of venereal disease in the barracks, they allow an unusual oversight of the conditions prevailing in regard to prostitution. The tables show that regulation of prostitutes on the basis of microscopic examination of the secretions has caused a striking reduction in the number of cases of gonorrhea. The proportion of cases of syphilis has not varied materially in the last ten years, averaging about 4 per cent., but the proportion of cases of gonorrhea has dropped from 25.6 to 12.6 per cent. It has ranged from 12 to 12.9 in the last five years. He thinks that the results obtained at Metz speak loudly in favor of systematic microscopic examination of the secretions in the official regulation of prostitution.

61. **Concentrated Carbolic Acid in Treatment of Scrofuloderma and Furunculosis.**—Vörner declares that he does not know of any method of treatment which can approach in efficiency the application of concentrated carbolic acid. For a small, still hard furuncle he touches the center with the acid. In larger ones he applies the acid with a fine needle or sound introduced into the central hair follicle or pore, inserting it as deep as he can. A single application is enough in most cases, but sometimes as many as eight are required. The application is made only once a day. He describes his experience with it in a number of cases, including two extensive carbuncles.

63. **Aspiration of Secretions from Accessory Cavities of the Nose.**—Meick presents a little apparatus which resembles a breast pump. A short glass tube fits into the nostril, the outer end connected with a glass bulb reservoir and also with a projecting tube carrying a rubber bulb. A hole in the nostril tube, just above the reservoir, allows it to be closed with the finger during aspiration, but the air can stream in at any moment in case the pressure becomes painful. This method of removing secretions from the nose and accessory cavities has abundantly proved its usefulness.

64. **Origin of Cancer.**—Bornmann analyzes the reasons for the conflicting findings of various investigators in the field of cancer, and remarks, in conclusion, that none of the so-called parasites are found in very small, young cancers. The reason for this is that these so-called parasites are, in reality, the relics of degenerative processes in the cells, and these processes do not occur early in the younger new growths.

65. **Camphor Treatment of Erysipelas.**—Mayer reiterates that sixteen years of experience with Pirogoff's method of treating erysipelas have only confirmed him more and more in his high opinion of it. He gives, every hour or second hour, .15 gm. triturated camphor, with hot drinks to promote sweating, and the usual external measures.

71. **Epidemic of Typhoid Among Children.**—The public schools at Deggendorf are attended by 1,009 children. About 200 of the poorer children are given their lunch at a soup house established for the purpose. Two of these children were taken sick, December 10, and staid at home, and about ten days later fifty of the others were also affected in the course of nine days, the sickness proving to be typhoid fever in all. The children lived in different parts of town, with scarcely any communication between the families. This epidemic of typhoid among the children eating at the soup house was fatal in two instances. The total number of children affected was 61, while only 43 adults in town and 31 in the adjoining country were affected during the same winter. No children were affected except those who had eaten at the soup house; the drinking water and milk there were above suspicion. A very few scattered cases of typhoid generally occur every year at Deggendorf.

77. **Atypical Leukemia.**—Preiss expatiates on the importance of an early diagnosis of leukemia and allied states in view of Roentgen treatment, which is capable of inducing such pronounced and prolonged improvement that it can almost be regarded as a complete cure. He describes 2 cases of atypical leukemia. The blood picture suggested myeloma, but the affection had nothing in common with that disease. In the

majority of such cases there is lymphatic metaplasia of the marrow of the bones, which is the cause not only of the existing lymphocytosis, but also of the appearance of increased numbers of normal and pathologic cell forms of the myeloid tissue. His first patient was a young man who was suddenly taken sick with pallor, pains in the bones and weakness, with great enlargement of the spleen and lesser of the liver, slight swelling of the glands and retinal hemorrhages, with a high degree of anemia, anemic changes in the reds and preponderance of young forms. The patient died in less than six months. Roentgen exposures of the spleen alone almost entirely banished the leukemia quantitatively about three months before death, while the blood findings became those of pernicious anemia. Before this the blood findings were a mixture of those characteristic of both lymphemia and myeloma. The blood findings in the second patient, a man of 59, also showed the same blending of anemic and leukemic characteristics, but there were no signs of pernicious anemia. The enlarged spleen became reduced in size under Roentgen exposures. The disturbances in this case had been noted for three years, and the patient had both syphilis and malaria in a mild form in his previous history. Prüss regards this case as one of lymphadenoid splenic pseudo-leukemia at first, with gradual formation of lymphomata in the liver and bone marrow and possibly transformation of the disease into lymphatic leukemia. The patient is still under observation.

78. *Atony and Chemistry of the Stomach.*—Kaufmann relates his experiences with 21 patients and with a number of normal subjects in researches on the chemistry of the stomach. His conclusions are to the effect that the figures for the total acidity and for the free HCl, which are given in the text-books as the normal values, are merely the averages. In reality, these values may range under normal conditions from 5 to at least 90 and sometimes over 100 for the total acidity without any indications of disturbance in the stomach functions. The figure representing the free HCl may likewise range normally from zero to at least 2 or even 3 per thousand. He then reports examinations of over 100 patients with various stomach affections which have demonstrated that cramps, acid eructations, acid vomiting and "heart burn" are more frequent when the stomach acidity is above the average, but still within normal range. Some other factor must be involved to produce the troubles of so-called hyperacidity besides merely the increased amount of the secretion. Whenever a patient is encountered presenting the symptoms of hyperacidity or other chemical gastric trouble the physician must seek for the second pathologic factor which forms the connecting causal link between the chemical findings and the subjective disturbances. In many cases this second factor is obvious in some ulceration, erosion or similar lesion. In these cases the time-course of the secretion may be regarded as the second concurring factor. In other cases, by far the most frequent, atony of the stomach will be found to be this mysterious second factor. Among 53 cases Kaufmann found pathologic dilatation of the inflated stomach in all but 18. When the acidity is a little above the mean average, then the patient presents the symptoms of hyperacidity; when it is a little below the average, the symptoms are those of subacidity or atony. In every instance the disturbances were cured when the musculature of the stomach had regained its normal muscular strength, no matter whether the acid secretion had been reduced to the mean average or not, or still persisted in the extremes first noted. In none of his other patients could any anatomic lesion or atony of the muscles be discovered. Such cases always proved to have been cases of neurasthenia alone, as all disturbances ceased when the neurasthenia had been cured by appropriate measures. The objective findings in these cases were normal. The secretions had not been abnormal, but the stomach mucosa was abnormally sensitive. This hyperesthesia forms the connecting link between the secretory anomalies and the stomach troubles. Better than by dieting or drugs to act on the secretions, such patients are cured by bromids, "water cures," hydrotherapy and forced feeding with coarse, mixed foods. The figures representing the acidity may persist unmodified, but the patients are cured as their stomach loses its excessive excitability.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

PREVENTION AND CURE OF TUBERCULOSIS. A Collection of Articles of a Popular Character on the Subject of Tuberculosis. By S. A. Knopf, J. H. Hurdston, D. A. Wilder and Others. Compiled by J. R. Long. Cloth. Pp. 246. Price, \$1.25. Denver: H. M. Brinker, 1905.

DIAGNOSIS OF TUBERCULOSIS OF THE LUNG. With Special Reference to the Early Stages. By K. Turban. With an Introduction by Sir H. Dunlop, M.D., LL.D., F.R.C.P. Edited by E. C. Morland, M.D., B.Sc. Cloth. Pp. 135. Price, \$2.00. New York: William Wood & Co.

LECTURES ON CLINICAL PSYCHIATRY. By E. Kraepelin. Authorized Translation from the Second German Edition. Revised and Edited by T. Johnstone, M.D. Second Edition. Cloth. Pp. 352. Price, \$3.50. New York: William Wood & Co.

THE PATHOLOGY OF THE KIDNEY.

SOME GENERAL CONSIDERATIONS.

W. T. COUNCHMAN, M.D.

BOSTON.

There are few organs in the body in which both structure and circulation are so complex as in the kidney. There is some variation in the size of the kidneys, depending on the life of the individual. The increased exercise of function as in potatoes is accompanied by increased size. The congenital anomalies are chiefly those of position and do not especially influence either its structure or function. In the congenital absence of one kidney we find in the other practically the same tissue arrangement, but the amount is doubled. In no other secreting organ do we find such differentiation of structure as that represented by the glomeruli and tubules. It is possible to think of the tubules not only as glandular secreting organs with a remarkable differentiation of epithelium in different parts, but as serving simply as the excretory ducts of the glomeruli. No other organ in the body has precisely the same character of vessels or the same circulation as the kidney. The blood supply to the organ is enormous. Landergren has estimated that in a minute's time under the action of strong diuretics the amount of blood which passes through the kidney is equal to the weight of the organ. That is, an amount from four to nineteen times as great as the average supply of the other organs. Regarding the vessels of the glomeruli as capillaries from which they differ, however, in several respects, the blood pressure within them must be high, because they spring directly from arteries of relatively large caliber. The pressure outside them is low because the space about them is protected from tissue pressure by the capsule. In the interior of the tubules there prevails normally the same low pressure, the circular wall of the epithelium preventing the action of tissue pressure. While it is true that the secretory pressure is usually low, various pathologic conditions show that the secretion can take place against greatly increased pressure. After passing through the glomerular vessels the blood again enters a series of long capillaries. How numerous these capillaries are can only be appreciated by the study of the injected kidney. From the capillaries the blood enters into numerous thin walled veins in which the pressure is low, and current slow, the pressure having been almost obliterated by the two capillary systems which intervene between the arterial pressure and the veins. The tendency of foreign cells, and, in certain cases bacteria, to accumulate within the veins is due to the slowness of the current.

There is a marked capacity for repair of injury in the kidney and but little capacity for perfect regeneration of tissue. The general law of the inverse relation

between high differentiation of structure and capacity for regeneration holds good in the kidney, as does also the law that capacity for both regeneration and repair diminishes with age. After extirpation of one kidney the remaining organ fulfills the function of both and does this by increase of tissue by growth. Epithelial cells become larger and more numerous, tubules larger and longer, and glomeruli larger, but after the completion of development there is no new formation either of tubules or glomeruli. The embryonic development of the kidney is delayed until some time after birth. The completion of development is readily recognized by the absence of embryonic glomeruli. The study of the kidneys in a large series of children who died of diphtheria showed embryonic glomeruli constantly present at two years and rarely present up to the sixth year.

The physiologic function of both kidneys is the same. The activity of secretion depends on the rapidity of blood flow through the organ, and on the activity of the renal epithelium. There seems now little doubt that there is a differentiation in the secretory function of the kidney in that the water of the urine comes chiefly through the glomeruli and the solids chiefly through the epithelium of the tubules. It is also true that certain portions of the tubules differ in function. The rapidity of blood flow through the kidney is regulated both by the general arterial pressure and by the varying degrees of dilatation of the renal arteries. Under normal conditions the kidneys discharge from the body the products of tissue waste represented chiefly by urea. They regulate also the concentration of the blood; their activity is excited by an increase in blood volume due to an increase of water. Under conditions of disease they remove from the body certain abnormal soluble substances, whether these are introduced from without or formed in the body as the result of defective metabolism or by the action of bacteria.

The kidney, like the other tissues of the body, shows various impairments of structure in old age, consisting in destruction or degeneration of the secreting structure, accompanied by increase in connective tissue. In the interpretation of these senile changes we are confronted with the usual difficulty of determining how much they are due to interference with circulation from the constantly accompanying arterial disease, and how much to the gradual wearing out of tissue. To these causes must certainly be added the accumulated effect of slight lesions with the constantly increasing inability of repair. These slight lesions, though of themselves relatively unimportant, may gradually increase the initial damage by interfering with the circulation or in other ways. Under normal conditions, aside from the imperfectly understood cases of physiologic albuminuria, no albumin appears in the urine. Its presence is usually an indication of damage to the glomerular epithelium. Although such cases are rare, it would seem possible in a purely focal inflammatory lesion of the

pyramids for an albuminous exudation to enter the tubules. How dependent the presence of albumin is on damage of the glomerular epithelium is shown in cases of the common acute non-suppurative interstitial nephritis of the infectious diseases. A high degree of this leading to marked changes in the tissue may be present without any involvement of the glomeruli and without albuminuria. The published cases of acute nephritis without albuminuria are probably of this character. The epithelial covering of the glomerulus is probably easily damaged and easily repaired.

The most easily understood lesions of the kidney are focal in character and due to the presence of bacteria in the tissue. The infection may be either hematogenous, the bacteria entering from the blood stream, or urinogenous, the bacteria entering from the urinary passages. The latter affections may be either ascending, from the bladder and ureters, or descending from a focus in the cortex. Bacteria often pass through the two capillary systems and lodge in the veins of the pyramids. This is particularly the case in hematogenous infections by the staphylococcus aureus. In this connection comes the question of the passage of bacteria through the intact epithelium. Experimentally this has not been shown to take place. It is true that in certain of the infectious diseases, notably in typhoid fever, bacteria are found in the urine, but it has not been shown in these cases that the kidneys are intact or that the bacteria come from the kidneys. That the kidneys may be injured by interference with the circulation is also evident. The pressure in the veins of the kidney is low and the exit of blood must be interfered with by obstruction in front, as in chronic passive congestion. The kidney is also damaged by obstruction of the urinary outflow. The damage here results both from the effect of the increased pressure within the tubules and on the epithelium and from the interference with the circulation produced by the increased tissue pressure within the kidney and the increased pressure in the pelvis. It is not possible to consider arterial hyperemia of the kidney as a pathologic condition. The blood supply of the kidney is regulated by the activity of the organ. That the activity may be excited and the blood supply increased by the presence of substances in the blood which are excreted by the kidney is evident, and also that such substances may damage the organ by injuring the epithelium of glomeruli and tubules and the endothelium of the blood vessels. The hemorrhages which are frequently found in connection with acute toxic hyperemia are due, not to the increased pressure, but to endothelial injury.

How the varying degree of damage to the kidney which constantly accompanies diffuse arteriosclerosis is brought about we do not know. These changes consist in degeneration and destruction of parenchyma and increase in interstitial tissue.

It is generally accepted now that the interstitial change is secondary to the damage of the parenchyma. There is no evidence in favor of a general fibrosis or independent increase of connective tissue in arteriosclerosis. There is, of course, in arteriosclerosis interference with the circulation, loss of regulatory power of arteries, increased arterial pressure, the injurious effect of substances in the blood due to deranged metabolism elsewhere, and the constantly increasing effect on the kidneys themselves, of their impaired action. It is probable that the condition in the kidneys is due to the combined effect of a great many factors rather than to any single one.

The greatest difficulty in understanding the pathology of the kidney is found in the acute, subacute and chronic diffuse lesions of the kidney not due to alterations in the flow of either blood or urine, nor to the immediate action of bacteria.

The acute interstitial non-suppurative nephritis gives the least trouble. It is found in acute infectious diseases, notably in the acute exanthemata, and consists in the presence in the blood vessels and interstitial tissue of the kidney of cells belonging to the lymphoid series which are formed in the bone marrow, spleen and lymph nodes, and which are brought to the kidneys by the blood. They accumulate in the renal veins, pass from these into the interstitial tissue and proliferate actively in both places. To what their accumulation in the renal veins is due, whether to an attraction exerted by the kidney or to the mechanical conditions of the circulation, I do not know. Unless the cell accumulation is so great as to interfere with the circulation or nutrition they need not give rise to any interference with function, though usually degenerative changes in the kidney due to the toxins of the disease accompany the interstitial changes. These cells never accumulate in the capillaries of the glomeruli, but are found to a slight extent in the capillaries of the cortex and chiefly in the veins of the pyramids.

Degeneration of the epithelium of the kidney varying in character and in degree is the most common condition found in all cases of diffuse nephritis. It is often exquisitely focal, affecting groups of tubules. It often shows a remarkable selection. Thus the degeneration which is constantly found in diabetes only affects the cells of Henle's loops. In cases of diphtheria I have found hyaline degeneration with extensive cell destruction confined to the proximal ends of the convoluted tubules. The degeneration may vary from such slight alterations of protoplasm or nucleus up to complete necrosis. The injured cells, entire or in fragments, may be desquamated and make their appearance in the urine. The degeneration may be the only change or be accompanied by extensive alterations of structure. If the degeneration does not affect the glomerular epithelium it may not be accompanied by albuminuria. Extensive degeneration may produce but little change in the microscopic appearance of the kidney.

Of the more severe lesions of the kidney due to the diffuse action of soluble substances, one group may be separated in which the lesions in the glomeruli are the most obvious condition. Severe lesions of the glomeruli do not occur alone, for they are all of such a nature as to interfere with the circulation in the glomerulus, and as the circulation of the kidney demands that the chief mass of its blood must first pass through the glomeruli, any interference here is felt in the remainder of the organ. The glomerular changes are varied. One of the most interesting is the obstruction of the vessels by peculiar hyaline thrombi, which Flexner interprets as being formed by agglutinated red blood corpuscles. This condition is rare, and I have found it most often in cases of staphylococcus septicemia, but the most marked case was in a kidney from acute plague which was sent from Manila. The most common cause of the glomerular affections I believe to be acute infections. Some organisms seem to be more inclined to give rise to them than others. They are found in the acute exanthemata, and are due, not to the specific agent of the disease, but to the organisms of the secondary infections. We have had a number of cases of glomerular nephritis, in which

the accompanying infection was acute endocarditis, due to the pneumococcus. The condition is not due to the direct action of bacteria, but to the action of toxic substances produced either by the bacteria or by the tissues. The glomerular affections may be acute, subacute or chronic. Clinically, they are usually accompanied by edema, the relation of which to the nephritis is imperfectly understood. The chronic cases lead to a small, fatty rather pale kidney with an irregular surface, to which the capsule does not cling closely.

The other form of chronic nephritis (chronic diffuse, chronic interstitial nephritis), slow in process, marked by slow destruction, affecting all parts of the kidney, but the glomeruli least and usually secondarily, with a marked increase in connective tissue, which of itself increases the damage, is most usually accompanied by arteriosclerosis.

The disease is composite; not one organ, but many are affected. The determination of the inter-relation of renal disease with defective metabolism, bacterial poisons, vascular and cardiac disturbances, dropsy and edema, lowered resistance to infections, must continue to be one of the paths along which investigation and experiment leading to exact knowledge must follow. The possibility of the production in animals of renal diseases, offering much similarity to those of man, which has been shown, is sure, by giving a field in which investigation can be more exact, to lead to advance of knowledge.

A question of great interest from both the clinical and pathologic point of view is that of the origin of tube casts. I think it is certain that these may be formed directly from the cells of the convoluted tubules by hyaline degeneration. Balls of hyaline material appear in the swollen cells, which finally break down, and the separate masses fuse together and pass into the lumen. This hyaline degeneration, though common in all pathologic conditions, is most marked in amyloid disease, and in the acute infections in which the highly refractive waxy casts are found. Casts into whose formation fibrin enters may be formed by an inflammatory exudation coming from the glomeruli or tubules. It is also possible that casts may be formed from a change in albumin during its passage through the tubules. The first two methods of formation are certain, though they will not account for the casts in all cases. The granules in the granular casts I think always come from the partial or complete disintegration of epithelium.

I present here some of the results which have come from the anatomic study of the cases of nephritis taken from the autopsies of the last ten years at the Boston City Hospital. The autopsies are carefully carried out, all organs are described and weighed and cultures made. The description embraces both the macroscopic and microscopic conditions, and the sections are preserved for future reference and control. The routine microscopic examination embraces the kidneys, liver, spleen, heart, lungs, pancreas and lymph nodes, and is extended to all pathologic conditions found outside of these organs. In going over these autopsies I have in many cases rejected the autopsy diagnosis on referring to the preserved sections, particularly in cases in which chronic interstitial nephritis was diagnosed. If the diagnosis of chronic interstitial nephritis is made in all cases which show some degree of atrophy of parenchyma and increase in interstitial tissue, few individuals over 50 escape it.

The diagnosis must be made from a consideration of the extent, the degree and the diffuseness of the lesions. I have only considered those cases as chronic interstitial nephritis, in which there was diffuse atrophy of the cortex, generally associated with decrease in weight of kidney, adhesion of capsule and irregularity of the surface. Glomeruli, as well as tubules, are affected, the main lesion being degeneration with atrophy. It is seldom that all parts of the kidney are equally affected. Enormously hypertrophied glomeruli and tubules are found along with those which have undergone atrophy, and the anatomic examination will not enable us to say to what degree this compensating hypertrophy has restored function. That it may do so seems apparent from the frequency with which the condition is not diagnosed clinically.

In the ten years there were 80 cases of chronic interstitial nephritis; 33 in females, 47 in males. Four of the cases were under 20, the youngest being a child of 2 years, in which there was a combination between acute non-suppurative interstitial and chronic interstitial nephritis, the condition following scarlet fever. The heart in this case was hypertrophied, weighing 165 grams. But little importance can be attached to the age, owing to the rarity of autopsies on children. Taken as a group, the cases show a considerable degree of heart hypertrophy. The cases are included in which the hypertrophy was accentuated by causes outside of the kidneys. In the 33 females the average weight of the heart was 412 grams. There were four marked exceptions to the hypertrophy. In one, aged 48, the kidneys with advanced interstitial atrophy weighed 165 grams, and the heart 275 grams. In one the heart weighed 200 grams, the kidneys 180 grams; in one there was typical interstitial with marked atrophy and death from uremia, the kidneys weighing 110 grams and the heart 260 grams; and in a case, aged 65, the heart weighed 260 grams, with kidneys weighing 210 grams. The males showed about the same degree of heart hypertrophy, the average weight of the heart in the 47 cases being 494 grams. Here also there were exceptions. In one case in a large individual the heart weighed 390 grams, and the kidneys, in which the lesions were of high degree, weighed 165 grams. Two of the cases of males without heart hypertrophy were senile with atrophy of all organs, and in another case the renal lesions were not of great degree. There were four hearts of over 700 grams, and in six others the weight was over 600 grams. Without exception in both males and females, the largest hearts were given by the combination between arteriosclerosis and chronic interstitial nephritis in large and well-nourished individuals. There is a close association between arterial disease and chronic interstitial nephritis. Which of the two conditions should be regarded as the primary and which the secondary, or whether they should both be regarded as parts of a whole can not be determined by anatomic investigation. It is certain, however, that the conditions can exist separately. Among the cases many can be selected which show both a high degree of arteriosclerosis involving even the renal arteries with but little change in the kidney and *vice versa*. The extreme degrees of atrophy in renal tuberculosis show no relation to arterial disease.

Closely associated with chronic interstitial nephritis are the cases of amyloid infiltration. The amyloid may be limited to the glomeruli and the different vessels or it may be more generally deposited. It may occur in

kidneys as simply superadded to chronic interstitial changes or it may be the predominant lesion. With it there is always associated degeneration of epithelium, marked by presence of fat and hyaline, and a varying degree of atrophy. In the extreme degree of amyloid infiltration characterized by a small pale kidney with irregular surface, no tissue approaching normal character may be found. The most of the glomeruli are converted into completely amyloid masses, and all the tubules belonging to them are atrophied and replaced by connective tissue. The amyloid kidney is in one way separated from chronic interstitial nephritis, and that is by the absence of heart hypertrophy. Thirty-six cases of amyloid infiltration of the kidney were found, seventeen in females and nineteen in males. The average weight of the heart in females was 269 grams and in males 320 grams. In the females there were two cases in which some degree of heart hypertrophy was found. In one case there was extensive arteriosclerosis, chronic interstitial nephritis with amyloid and in the other case arteriosclerosis with slight amyloid confined to the glomeruli. In the males there was one case of hypertrophy, the heart weighing 525 grams. In this there was arteriosclerosis with aneurism and an osteomyelitis, to which the amyloid infiltration was probably due.

There were twenty-two cases of subacute and chronic glomerulonephritis. In this form of nephritis the lesions are certainly primary in the glomeruli and consist in changes which must interfere with their function by means of the cell degeneration and the occlusion of vessels. The term chronic parenchymatous nephritis, which is that generally used to designate the condition, is less descriptive of the lesions than is the term chronic interstitial nephritis, descriptive of atrophy with increase of connective tissue. It is difficult to estimate the relation of this lesion to heart hypertrophy, owing to the frequency of the association of heart lesions which in themselves should be regarded as causes of hypertrophy. Excluding such cases, the weight of the heart in males was 433 grams, denoting a considerable degree of hypertrophy, though much less than in chronic interstitial nephritis. There is one form of glomerulonephritis to which I wish to call attention. It consists in homogeneous thickening of the walls of the vascular tufts of the glomerulus, thereby narrowing the lumen. It may affect all the vessels or occur in patches, and may lead to complete obliteration of the entire glomerulus or of single groups of vessels. The thickened walls do not give the reaction of connective tissue in staining. The thickening is not due to the presence of demonstrable fibers. There was nothing in the histories of the individuals nor in the associated lesions to throw any light on the condition.

Acute glomerular nephritis (acute parenchymatous nephritis) was found in thirty-two cases, twenty-two male and ten female. The acuteness of the process was judged by the prevailing cellular character of the lesions and the absence or slight development of connective tissue. I have elsewhere called attention to the frequent association of this lesion of the kidneys with pneumococcus infections, particularly with acute pneumococcus endocarditis. In the numerous autopsies on acute croupous pneumonia only in two cases was there the complication of acute glomerular nephritis. Why this, the most frequent form of pneumococcus infection, should so rarely be accompanied by nephritis I do not know. Next to the pneumococcus the frequent associated infection is with the streptococcus pyogenes.

Cultures of the kidneys in these cases show the presence of the infecting organisms, but they can not be regarded as directly causing the lesions. The lesions are too diffuse to be regarded as produced by direct bacterial action, and when organisms are found on microscopic examination they are not associated with the lesions. None of the cases of typhoid were complicated by nephritis. Of all of the acute infectious diseases, acute endocarditis is most frequently accompanied by this most serious form of nephritis.

One of the most interesting forms of nephritis is the acute interstitial non-suppurative form. It has nothing to do with chronic interstitial nephritis, for this has no acute form, but is the result of a slow, progressive disease. Acute glomerular nephritis passes into the sub-acute and chronic form, and probably mild degrees are recovered from. Acute interstitial non-suppurative nephritis consists in the accumulation in the interstitial tissue of the kidney of large cells belonging to the lymphoid series which are brought to the kidney by the blood. The cells are generally in foci situated beneath the capsule, around the glomeruli, and just above the pyramids. Only in the most extreme cases is there a diffuse infiltration of all parts of the kidney. There may be very considerable lesions without producing any easily recognized changes in the microscopic appearance of the kidneys. When the lesion is very pronounced and diffuse, the kidney is greatly enlarged, the capsule is tense, the markings are obscure, the tissue pale, succulent and resembles the section of a lymph node in lymphatic leukemia. The largest kidneys I have found were 480 grams in a child of 3 years; 300 grams in a child of 5 years, and 250 grams in a child of 4. The chief interest in the condition of the kidneys is that the cell infiltration is not secondary to injury or degeneration. It may exist with normal epithelium. The glomeruli are never affected. The large cells, prelymphocytes, are formed in the bone marrow, spleen and lymph nodes. They enter into the blood and seem to be mechanically held in the slow capillary and venous circulation. It is evident that they migrate through the wall and proliferate both within the vessels and in the interstitial tissue, as is shown by the numerous nuclear figures in these places. Polynuclear leucocytes are only found among them when there is associated necrosis. There were found twenty-eight cases with this condition. All were in cases of diphtheria or scarlet fever, with the exception of one case, that of croupous pneumonia. I have elsewhere called attention to the frequency of acute interstitial nephritis in diphtheria and smallpox and discussed the origin of the cells.

The study of the pathologic anatomy of the kidneys has thrown but little light on the essential nature of those acute and chronic diseases in which lesions of the kidneys form a part of the pathologic process. It early led to a classification of the lesions and to a nomenclature which was intended to be expressive of their nature and histogenesis, but which is not. Even the term nephritis has come to mean merely a diseased condition of the kidneys. The anatomic study has led to a better appreciation of the extraordinary complexity of chronic disease and to a recognition of the interrelations of affected organs.

There are certain conclusions forced on one by the careful routine examination of the kidneys in a large number of autopsies. Probably the most important is that the lesions of the kidneys are only part of a whole. Almost invariably there are lesions in other organs

sometimes of the same general character as the lesions in the kidney, sometimes of a different character. We can not consider kidney disease as an entity. The injuries which are produced in the kidneys are either due to agents which are formed in the body as a result of disease in other organs or they enter the body from without, affecting the kidneys secondarily. Even the simplest lesions due to the direct action of bacteria are secondary to infections elsewhere. The frequency of lesions, especially when the examination is by the microscope as well as by the naked eye, is striking. Apart from the acute degenerations of epithelium which are almost constant in the acute infectious diseases, chronic lesions of greater or less degree are common, and with increasing age increase greatly in frequency and in degree. It is probable that we rarely pass through an acute infection without some injury being produced in the kidneys. When the injury produced is of such a character that perfect repair can not take place the evidences of it will remain. Slight injuries may produce no impairment of the renal function and there may be no means of clinical recognition by the usual tests of albumin and casts. Provided the injury leads to complete destruction of glomeruli and tubules with consequent absence of function in the part affected, as in the case of an infarction, neither casts nor albumin may appear in the urine, though the remaining tissue be insufficient for the work of the organ to be accomplished. On the other hand injuries which have not led to complete destruction and where the injured tissue functions, though imperfectly, will be accompanied by the clinical evidence of albumin and casts. The presence of albumin and casts may simply mean that a part, and often a very small part, of the tissue is functioning imperfectly, though the whole amount of renal tissue and function may be ample. Anatomically it is not uncommon to find casts in a few tubules connected with foci of injury, the remainder of the tissue being perfectly normal. Comparing clinical reports of routine urine examinations with the results of routine necropsies, it often appears that too much importance may be attached to the presence of albumin and casts, though they always mean injury of the organ. Too much importance can not be attached to the results of urinary examination directed to the ascertaining of kidney sufficiency. In cases of acute interstitial nephritis of high degree with compression of tubules and destruction of epithelium, the routine clinical examination has often given only the common "slight trace of albumin" and the anatomic examination showed no casts in the tubules. In such cases it has seemed sure that the function of the kidney must have been impaired, though the clinical examination gave no evidence of it.

It is difficult to understand the association of lesions, which is shown at autopsies. Thus we know that in the great majority of cases atrophy of the kidneys will give rise to heart hypertrophy. The average weight of the heart in chronic interstitial nephritis is far above the weight of the heart at corresponding ages. But there are many exceptions even to the association between renal atrophy and heart hypertrophy. We may find a great degree of heart hypertrophy associated with slight atrophy, and a great deal of atrophy with but slight change in the heart. It is not uncommon to find in hydronephrosis or in chronic pyelonephritis or in chronic renal tuberculosis extreme renal atrophy with a heart of normal size. The absence of heart hypertrophy in renal atrophy is particularly striking in the case of

amyloid disease. Even the association of such conditions as renal atrophy and arteriosclerosis, which, in the absence of amyloid, seem sure to lead to heart hypertrophy, fail to produce this if any degree of amyloid infiltration be present. At present we are without any acceptable hypothesis in explanation of this association, and the number of hypotheses which have been advanced serve to show our ignorance. The same thing is true in regard to edema. We are accustomed to think of the association of certain forms of nephritis, particularly those involving the glomeruli, with edema, but the exceptions are almost as frequent as the rule.

It is not probable that much light will be thrown on the numerous obscure questions relating to nephritis by anatomic investigations. The work which has been done in pathologic anatomy in chronic disease is imperfect and has consisted chiefly in making artificial classifications and giving these names. The study of the histogenesis of lesions has been fruitful in enabling us to ascertain the general sequence of lesions, but has thrown little light on their causes and interrelations. At an autopsy even under the best conditions it is impossible, in the absence of definite questions, for the routine examinations in every territory to be so fully carried out that they will shed much light on the disease. The questions which are present to the pathologist and which he endeavors to answer in his work are not the same as are presented to the clinician by his study of vital phenomena, and the clinician can not take the observations of the pathologist and seek by them to answer his questions. The observations of the pathologist are directed by a different set of questions. What is needed in the study of chronic disease is not the attempted analysis of numbers of cases and dividing them into groups, but the careful placing of questions by the clinician and pathologist and the thorough study of individual cases by clinical, pathologic, chemical and anatomic methods. The questions should be divided into their simplest components, and the hypotheses derived from study should be tried by animal experiments. The acute infectious diseases seemed more obscure than did chronic diseases before their etiology was ascertained, and even with this and the possibility of simple direct animal experimentation the knowledge which has enabled us to form acceptable hypotheses in explanation of certain acute infectious diseases has come but slowly. Knowledge of chronic diseases which will enable us to form acceptable hypotheses in explanation can come in no other way.

THE RELATION OF THE KIDNEYS TO ECLAMPSIA.*

PHILIP KING BROWN, M.D.
SAN FRANCISCO.

The sources of my information for this paper are:

1. Statistics from hospitals and private sources on eclampsia and kidney conditions.
2. The literature on eclampsia and metabolism.
3. Personal observations on urea elimination in pathologic conditions of pregnancy.
4. Experiments on the muscular irritability of pregnant and non-pregnant animals.

From the 51,010 records of births in which I could get at least a few important data concerning the frequency of eclampsia in cases of nephritis, renal irritation and

*Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

toxemia, and the frequency of these conditions without eclampsia, the following facts are shown:

The proportion of eclamptics to births is 1 in 105 cases.

Eighteen and two-tenths per cent. of the eclamptics whose urine was examined just before or after convulsions showed only evidences of "renal irritation" in the urine.

Eighty-one and eight-tenths per cent. showed "nephritis" under the same conditions. "Nephritis" was defined on the circular sent to physicians and hospitals seeking information, so as to include cases showing 0.1 per cent. of albumin and casts, or less marked urinary findings with marked edema of the body. "Renal irritation" included cases with no edema and less marked urinary findings, while "toxemia" included the cases of headache, vomiting, dim sight or abdominal pain (other than labor pain) near the time of delivery.

TABLE 2.

SUMMARY SHOWING RELATION OF KIDNEY CONDITIONS TO ECLAMPSIA IN CASES WHERE FULL DATA WAS OBTAINED.

Eclamptic cases with nephritis before or after convulsions.	228
Eclamptic cases with renal irritation only before or after convulsions.	51 (18.2%)
Eclamptic cases with nephritis or renal irritation before or after convulsions (data not enough to classify).	127
Eclamptic cases with no record of urinary findings.	498
Eclamptic cases with "renal irritation" only.	514
Non-eclamptic cases with normal urine.	10,360
Non-eclamptic cases with "nephritis."	196
Non-eclamptic cases with "renal irritation" only.	787 (7.5%)

Of the non-eclamptic cases in a series in which 10,360 had normal urine, there were 196 cases of nephritis and 787 of renal irritation.

The full table shows the marked variations in the frequency with which these symptoms occur in different hospitals—depending probably on the care with which the urines are examined in each place. The column marked "eclamptics-urine recorded negative before convulsion"—is significant. The 4 cases recorded in the Boston Lying-in figures may possibly be accounted for by the careless work of students who do the out-patient work. The Johns Hopkins case is specially referred to by Dr. Little as a case where the only record of urine examination before the attack was the statement "urine negative." Dr. A. Brown's case was one in which the patient's urine was free from albumin a week before the attack. Immediately following the examination, the patient caught a severe cold and had temperature for several days prior to the eclampsia. The urine was not examined again until after the attack. That albuminuria is a more frequent accompaniment of pregnancy than these figures indicate is well shown by the examinations of Little of Johns Hopkins and of Trautenroth. Their results are shown in Table 3.

This makes it clear that the kidneys show the strain of the pregnancy and labor by an elimination of albumin in practically every case. In a vast majority of the cases there is nothing to show that this strain is significant of more than the similar appearance of traces of albumin and occasionally casts in the normal individual after exercise. Darling has shown that albumin enough to coagulate solid on boiling may result in the urine of a previously normal person from the prolonged strain of a boat race, and that practically all athletes show traces of albumin and casts after prolonged effort, even when accustomed to it.

TABLE 3.

TABLE OF STATISTICS SHOWING FREQUENCY OF ALBUMINURIA IN PREGNANCY WHERE THE SUBJECT WAS RECEIVING SPECIAL INVESTIGATION.

Urine in	Pregnancy.		Labor.	
	Little (Johns Hopkins.) 715	Trautenroth, 100	Little (Johns Hopkins.) 550	Trautenroth, 39
Negative	49.2%	50.5%	37.4%	14%
Albumin	48.8%	45.5%	42.9%	89%
Albumin and casts	10.1%	4.0%	18.5%	43%
Casts, no albumin	1.9%			28%

LITTLE (JOHNS HOPKINS) IN SPECIAL SERIES OF 100 CASES.

	Pregnancy.	Labor.
Negative.	54%	10%
Albumin.	46%	89%
Albumin and casts.	14%	43%
Casts, no albumin.	1%

The albumin may mark a pathologic condition of the kidney arising during pregnancy or the exacerbation of an old kidney lesion. The occurrence of albumin in large amount so constantly with eclampsia suggests a dependence of both on some common cause. Trautenroth has shown that the death of the fetus in utero has stopped a marked albuminuria, and Strumer reports a remarkable case of a seventh pregnancy in a woman who had eclampsia in her second and fourth confinements. Her other pregnancies had been normal. At time of admission the urine was scanty and loaded with albumin, both feet edematous, and she had headaches. A milk diet and 15 grains of thyroid extract a day resulted in the disappearance of all symptoms in 9 days, including the albumin. She left the hospital under protest, but was brought back 11 days later, having just had 3 convulsions.

The occurrence of casts far more frequently in the urine of multiparæ than in primiparæ is a strong argument against the renal origin of the eclampsia poison for 80 per cent. of the cases of eclampsia occur in primiparæ, according to German statistics, where the prior kidney condition is more favorable. Lange finds also a common extra-renal cause for a number of the phenomena of the toxemia of pregnancy, particularly the albumin. He shows that the ordinary thyroid enlargement during pregnancy disappears under administration of thyroid, increasing again at the cessation of the treatment. In the 133 cases examined for thyroid changes, 3 were doubtful, 108 showed this enlargement, of whom 2 only had albuminuria. One of these was nephritic, and one developed eclampsia. In the remaining 22 where there was no enlargement, 20 had albuminuria, 16 with casts, and 6 of these developed eclampsia. Lange removed one-fifth of the thyroid in 10 pregnant cats; 2 died in coma 23 and 38 days after operation, 3 had convulsions 23 and 25 days after operation. Of these 5, 3 had albuminuria and fatty changes were found at autopsy in the liver and kidneys. No changes were noted in the other 5 cats during the pregnancy, but, on examination after they were killed, similar changes were found in the organs of 3.

The theory on which eclampsia was first held to be dependent on kidney disease was, of course, this association of albumin with the attacks and the similarity of the convulsive seizures in eclampsia to uremic convulsions. I have tried to make it plain that albuminuria is almost the rule in pregnancy, particularly at the time when eclampsia occurs, and that even severe nephritis and extreme albuminurias occur commonly without signs of eclampsia. Renal insufficiency with retention of toxic waste products, increased by the incident of pregnancy, was the explanation which arose from this conception of eclampsia. Urea naturally held the first place as the toxic agent, as it makes up so large a part of tissue waste and was so long associated with uremia as its cause. Because this view still lingers with some few, I have shown on diagrams the extreme variations in the excretion of urea in 3 cases of pregnancy—the first a case of post-scarlatinal nephritis, with marked edema and an amount of albumin varying from 0.1 per cent. to 1.6 per cent. in the last month of pregnancy and the month after it; the second, a case which had had eclampsia in two previous pregnancies and had a trace of albumin with casts in this pregnancy; the third, a normal case on full diet for comparison. These first two cases were put to bed on a milk diet while these observations were made. The case which had previously had eclampsia also underwent this régime for three periods of 10 days each during the earlier part of her confinement.

CASE 1.—Mrs. W. B. First pregnancy. Scarlatinal nephritis since childhood. Urine found, early in pregnancy, to contain nearly 0.1 per cent. of albumin, with hyaline, granular and epithelial casts. The patient was brought to San Francisco and kept in bed and a diet given her, consisting solely of milk, for 4½ weeks before her confinement and for nearly a month after it. Chart I illustrates the gradual increase in the amount of albumin and the decrease in the urine and the urea, and their extreme variation. It shows further the striking increase in the urine and urea after confinement. That pregnancy is a very severe tax on such a case there is no doubt, although this particular patient bore a second pregnancy two years later without having at any time over 0.1 per cent. of albumin. It is a significant point that on the days of free movements of the bowels, when the urine and urea elimination was low, the percentage of albumin increased strikingly, more than doubling on several occasions.

CASE 2.—Mrs. L. (Chart 2). Has twice had eclampsia at 7 months. Her urine at the beginning of the third pregnancy was found to contain but a minute trace of albumin and a few hyaline and granular casts. For periods of 10 days each, during the middle of the pregnancy, the patient was put to bed on a milk diet amounting to nearly 4 quarts a day, and estimations were made of the functional activity of the kidney in quantity of urine and urea eliminated. For a month before the confinement the patient was kept constantly in bed on the same diet. Here again it is shown that the urea relatively and absolutely diminished steadily up to the day of confinement, after which there was again a striking increase in both the total urea-nitrogen and percentage of urea. The patient was delivered without convulsions.

CASE 3.—Normal case. A normal case is charted for comparison. The patient was on full diet (Chart 3).

Two facts are shown plainly:

1. The urea diminished markedly before confinement, even in the normal case. In the other two cases it was reduced steadily for a month before pregnancy to at least one-third the normal amount and on certain days got as low as three grams. Both of these cases belong to the class of renal insufficiency with retention of urea, but both were confined without convulsive manifestations.

2. They illustrate also the fact that after periods of retention the urea is usually correspondingly increased for a time. This has been shown also in hysterical anurias, where again no convulsions follow the long-continued retention of normal end products.

These three cases will serve to show the extreme fallacy of the urea estimations as evidence of the nitrogenous elimination of the patient, for I have no doubt that the feces during these periods contained a relatively increased amount of nitrogen and the urines themselves contained nitrogenous products in increased quantity in the form of ammonia, kreatinin and uric acid, as has been shown by Folin to be the case in normal persons whenever the urea is diminished. Folin shows, further, in a patient of his that had taken extremely little food for several weeks and no food for five days before the examination he made, that in 24 hours only 125 c.c. of urine was passed, and this contained .85 grams of nitrogen, and that only 14.7 per cent. of this total nitrogen was in the form of urea and 40 per cent. of it was in the form of ammonia. Normally 80 to 85 per cent. of the total nitrogen is in the form of urea and 3 to 5 per cent. of ammonia. Folin quotes a still more interesting case from an analysis by Möerner. This urine contained only 4.4 per cent. of the total nitrogen as urea, with 26.7 per cent. as ammonia. While no particular deductions can be drawn from these cases, they serve to show that the failure of the kidney to eliminate nitrogen in the form of urea has no special significance, that it depends entirely on diet and the amount of nitrogen eliminated in other ways. In my own experiences I have the records of a case of pernicious anemia with chronic diarrhea where for months not more than 5 ounces of urine were eliminated a day, but where intestinal sand consisting of uric acid was eliminated daily in enormous quantities. This diarrhea had gone on for 20 years, and the woman died of pernicious anemia at the age of 72. So much for the influence of deficient elimination of normal end products. I have not gone into the variations in the quantity of kreatinin, ammonia and uric acid, but the conditions under which they increase and decrease in urine in other pathologic states than eclampsia, without causing convulsions, render it most probable that they have nothing to do with this state.

It has never been found that any one of them was constantly increased in the blood of eclamptic cases.

Developments in the study of metabolism brought two new theories of eclampsia in which the kidney played some part. The first was that conditions hold in eclampsia whereby normal end products of metabolism were not formed. The liver notably has attracted attention in this particular. Animals in which the Eck fistula had been produced, thus cutting off the function of the liver of destroying or converting certain toxins, died of severe intoxications. None of the known intermediary

source of this increased toxicity of the blood is the present point in dispute among the legion of investigators of this subject.

I will not review the subject here, but will state simply that the recent work of Schmorl, Dienst and Liepman calls attention to the fact that the placenta of eclamptic cases are commonly pathologic; that there are large communicating spaces found in these placenta; that thrombi of placental cells are frequently found in the maternal veins (although they are found in non-eclamptics also); that the blood of the fetus in eclampsia has a hemolytic

CHART 1—PREGNANCY IN CHRONIC PARENCHYMATOUS NEPHRITIS.

CHART 2—COURSE OF URINE AND OF UREA IN THIRD PREGNANCY (NORMAL), ECLAMPSIA IN FIRST AND SECOND.

products, however, have been found to be increased in the circulation or urine, so the theory has little to support it. The second theory supposes from the analogy of B. oxybutyric and diacetic acid intoxication in diabetes, which is itself due to a number of causes, that a similar production of abnormal and toxic end products occurs in eclampsia. Bearing out this theory it has been shown definitely that the blood in pregnancy is more toxic than normal, and that this toxicity is further increased in eclampsia. All attempts to show an increased toxicity to the urine have thus far been unconvincing. The

action on the maternal blood, and, finally, that serum emulsions from dried placenta of eclamptics produce death in animals into whom it has been injected, whereas serum from normal placenta made in the same way is harmless.

Brettaner reports an interesting case bearing on the placental origin of the toxin. A woman of 40 who had had 3 difficult labors, was seized with convulsions without premonitory symptoms at full term. Two children were born, much asphyxiated, but they were resuscitated. The placenta was single; 6 hours later the first

child had a convulsion, followed in the next four hours by four more. Eight hours after birth the second child had its first convulsion, and nine others followed rapidly before death ended the attacks. The mother's attacks ceased with the birth of the children.

This case led me to investigate, as far as I could, the question of the size and number of the placenta in twin pregnancies. It may be a coincidence, but in 3 cases of twin pregnancies, where the mother and at least one child had convulsions, the placenta was single. And in 9 cases obtained from the records of Dr. Adelaide Brown, the only two cases that had no noticeable albumin in the urine during the pregnancy, were cases of double placenta. In the other seven cases, four had a large amount of albumin, three being regarded as critical cases of the nephritis of pregnancy.

In carrying out the investigations as to whether the nervous system of pregnant women was more responsive to stimuli than non-pregnant women, it occurred to me that the experiments of Loeb on muscular irritability might be applied with some interest of pregnant animals in the hope that further light would be thrown on the question of convulsions. Loeb found that if the fresh gastrocnemius of a frog were immersed in a solution of a

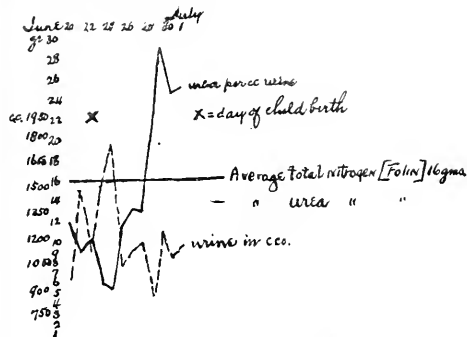

Chart 3.—Normal case for comparison.

sodium salt, the muscle will show immediate rhythmic contractions which cease when the muscle is immersed in a solution of calcium chlorid. He showed further that if the nerve alone be put into one of these salt solutions, the muscle begins to twitch in about five minutes and finally gets into tetanus. If the nerve be taken out of the solution, contractions cease. "Although this seems to indicate that the salts or other ions stimulate the nerve directly, it can be shown that they have only increased the irritability of the nerve, for when the nerve is brought in contact with any solid or liquid body the contractions of the muscles will be resumed." In furtherance of this suggestion I undertook the following experiment: An isotonic solution of sodium citrate was injected into the peritoneal cavity of pregnant and non-pregnant guinea-pigs. No convulsions were produced in either set of animals by small doses, but increasing the dose or the addition of a small quantity of barium chlorid to the sodium citrate caused immediate general convulsions in the pregnant animals and frequently death in doses that did not affect non-pregnant pigs, even of smaller size. The details of these experiments will be published later.

SUMMARY.

1. Albumin is present in fully 80 per cent. of normal pregnancies.

2. Albumin and casts are found in at least 30 per cent. of all pregnancies.

3. There is no reason to suppose that the renal condition thus revealed is the cause of eclampsia.

4. That there is some connection, however, between the albuminuria and the extra-renal cause of the eclampsia is likely, in view of the nearly constant association of the two.

5. It has been shown that neither any normal end product nor any known intermediary product of metabolism is the cause of eclampsia.

6. It is reasonable to suppose that deficient thyroid or parathyroid activity plays a part, at least, in some of the cases of eclampsia.

7. There are probably several causal factors to the separate or concomitant action of which eclampsia seems to be due.

8. The most significant experimental work done up to this time points to the fact that in the placenta are formed the toxic substances which probably are responsible for eclampsia.

9. There is good evidence that these same substances are, in all probability, the causes of the headache, edema, abdominal pain, and particularly the albuminuria present in non-eclamptic and non-nephritic cases.

10. The nervous systems of pregnant women are in an abnormally sensitive condition. Their blood has been shown to be abnormally toxic. There is no conclusive proof of an increased or diminished toxicity of the urine.

11. My own experiments have shown that the muscles of pregnant guinea-pigs can be thrown into convulsion more easily than those of non-pregnant animals.

CYLINDRURIA.*

CHARLES P. EMERSON, A.B., M.D.

Assistant Resident Physician in Charge of the Clinical Laboratory,
Johns Hopkins Hospital; Associate in Medicine, the Johns
Hopkins University.

BALTIMORE.

(Concluded from page 13.)

CHRONIC INFLAMMATORY NEPHRITIS. RED KIDNEY. ARTERIOSCLEROTIC KIDNEY.

Of the 104 cases studied, the combined kidneys weighed above 500 grams in 12 per cent.; from 400 to 500 in 18; from 300 to 400 in 31; from 200 to 300 in 33, and below 200 in 6 per cent. It is thus seen that these kidneys averaged much larger than the white kidney just described.

Kidneys Weighing Over 300 Grams.—In 46 of these cases the nephritis formed no part of the clinical picture and was not even mentioned in the diagnosis. The average weight of these kidneys was 412 grams, the cortex measuring from 4 to 7 mm. The urine was normal in amount and specific gravity. Albumin was present but in traces, if at all; the casts were few, absent in 18 cases at times, at least, yet in 10 cases hyaline and granular and epithelial casts were abundant at times. On some days many were present. In 8 per cent. albumin was absent for a time at least. While there is a rough parallelism between casts and albumin, the former are more variable.

In 19 cases the diagnosis was nephritis. The kidneys averaged 390 grams in weight; the cortex measured

*Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

from about 4 to 8 mm.; amount and specific gravity were normal. The albumin was often of fairly large amount, even 0.4 per cent. In 9 cases there was only a trace. The casts were almost constant (yet absent at times in 4 cases), or hyaline and granular.

Kidneys Weighing from 250 to 300 Grams.—In 23 cases the symptoms of nephritis were the subordinate element, in 16 cases the predominating element. The urine was practically the same in both groups. It is interesting to note, however, that the specific gravity ran a little lower than in the preceding group. The albumin varied in amount, and casts of all varieties were present, sometimes in enormous numbers. In the first mentioned group, however, they were often few and only granular and hyaline, while in the latter group waxy and epithelial casts occurred.

Kidneys Under 250 Grams in Weight.—Of the 22 cases in this group in 14 the nephritis was unimportant, while the other 8 were acute exacerbations. The kidneys averaged about 210 grams in combined weight and the cortex measured from 3 to 5 mm. The amount of urine was in all practically normal, also its specific gravity. Albumin was present in practically all cases, usually as a trace, but sometimes a fair amount. The casts were few as a rule, but often many granular and hyaline, and sometimes waxy (in 4), epithelial (in 4), and fatty (in 1) were found. Even in the smallest kidneys the urinary condition was not very similar to that of the small white kidney.

In all these cases an interesting feature is the fact that at the beginning of their admissions or in their previous admission, even back for several years, albumin and casts were practically always present. It will be remembered that in the white variety both albumin and casts were almost a terminal event.

CASES OF CHRONIC NEPHRITIS. NO AUTOPSY.

As is easily seen from the study of cases with autopsy, the condition of the kidney can hardly be suspected from the urine alone. We shall group the following cases by their clinical features.

(1) *Chronic Nephritis.*—In some cases there were no acute symptoms, except perhaps a slight edema. Such are cases especially associated with advanced arteriosclerosis or cardiac disease, which dominates the clinical picture. Of 126 such cases 36 patients died. Of the 90 who left the hospital, in 70 the urine was of normal amount, specific gravity almost normal perhaps slightly lowered, varying inversely as the amount, albumin a trace, often disappearing while in the hospital. The casts were almost all hyaline and granular, and in case the albumin or the casts disappeared while under observation it was in 75 per cent. of the cases the latter. We wish to emphasize this point. In 20 per cent. of these cases more than a trace of albumin was present, and even 1 gram per mille. Very rarely epithelial blood and waxy casts were seen. There was an occasional renal epithelial cell or blood corpuscles and leucocytes found.

Of these 36 fatal cases, on admission the patients presented the following features: In 9 there was a trace of albumin and in 3 none. The casts were hyaline and granular, and in 1 case a few epithelial were found. In 3 cases without albumin or casts at first, the casts appeared later. In 10 cases there was a measurable amount of albumin, as high as 0.2 per cent. In 3 of these no casts were found; in the others granular, hyaline and sometimes epithelial were present. In 9 cases there was over 0.2 per cent. albumin, and, in addition to hyaline

and granular, also waxy casts. On these cases at death the albumin was present in 12 cases in traces. In 4 of these it had diminished toward the end. Casts were hyaline, granular or none, and in any case only a few in number. In 14 cases the albumin at death was measurable but under 0.2 per cent. It had diminished in 3 of these cases and had increased in 2. The casts were few in number, hyaline, granular and in 1 waxy: in 1 case none. In 5 cases there was a final shower of casts. At this time the casts were almost all hyaline and granular, and a rare epithelial and fatty cast. In 8 cases the albumin was over 0.2 per cent., in 1 case 0.7 per cent. The casts were present in vast numbers in 3, yet here they were almost all hyaline and granular, with a few epithelial. This lack of variety of the casts, despite their immense number, would seem to indicate that this shower was due chiefly to vasomotor changes in the kidney preceding death and not to an intensification of the nephritic process.

(2) *Chronic nephritis in arteriosclerotic or cardiac cases* in which the patients had acute symptoms on admission, especially edema. Of these there were 57, 13 of whom died. Of the other 44 cases, in 26 the urine was practically the same as described above, except for a polyuria of even 6 or 8 liters which often occurred during the absorption of the edema or effusion. This was well marked in 35 per cent. of these cases. In 32 per cent. there was more than a trace of albumin. This often diminished or even disappeared while the patient was in the hospital. Of the 13 fatal cases, at the onset there were traces of albumin in 2, a small but measurable amount in 1, and over 0.2 per cent. in 3. There were large numbers of hyaline and granular casts. Toward death a trace of albumin was found in 4 cases; in 2 of these it had been more. These patients had often very many casts of practically all varieties. In 5 cases with more than a trace there was less than 0.2 per cent. albumin, in some many hyaline and granular casts and in 1 case none. In these cases the casts are a subordinate feature and if numerous there are only hyaline and granular found.

AMYLOID DEGENERATION.

Amyloid degeneration may be superimposed on any form of nephritis of which it really forms no part.

In the majority of cases the condition can not be suspected from the urine alone, although given a case with history and physical signs indicating it and the urinary changes may be well explained. Disregarding the clinical features the urine would suggest on the one hand, when concentrated, chronic passive congestion; on the other, small contracted kidney.

The following is the classical description of the urine: It is increased in amount, is pale, clear, faintly acid, of low specific gravity, from 1005 to 1012, and abundant albumin as a rule, with relatively much globulin, and very few casts. This picture of Traube, however, is rare. The albumin may be little or none and the casts may be numerous. They are often fatty. Waxy casts may occur here, but are not at all distinctive. Renal epithelium is rare; red corpuscles extremely so.

Of the 18 cases of which we have notes, in 9 the nephritic symptoms were the unimportant, and in 9 they were the important features. Nine of the pairs of kidneys weighed more than 400 grams; the smallest weighed 210. The cortex varied in thickness from 6 to 9 mm. The amount of the urine presented nothing peculiar; its specific gravity in the majority of cases (9 cases) was lower than normal and in only 3 did it reach 1020.

The amount of albumin varied, in 5 cases being present but in traces, while in 7 cases there was as much as 0.8 per cent.

The casts varied almost as much; sometimes there were many, sometimes few, in 2 none. In only 2 cases were waxy casts abundant, and there were epithelial casts in but 2. In 1 case with 0.2 per cent. albumin the examinations on six days showed but one cast. In the other cases, as a rule, they were few in number. In one case with 0.1 per cent. of albumin a few hyaline and granular casts were present on some days, on other days none.

RENAL ATROPHY.

This condition may be due to insufficient blood supply, to cachexia, to the anemias, and especially to advancing age, the senile atrophy. It is never great in amount. Microscopically sclerosed glomeruli are seen, but there is no great increase in connective tissue. The urine is practically normal and without albumin.

UREMIA.

We have abstracted the histories of 96 cases of nephritis with uremia. Of the 54 cases in which the first symptom of the nephritis dated back less than six months 42 patients died. Of the 35 cases with an old history of nephritis 29 patients died. Senator states that the amount of urine is diminished or there is even anuria; rarely does this fail, and more rarely is there polyuria at the onset.

Of 8 cases of terminal uremia the albumin was increased in all. In 1 case of uremia with a trace of albumin on the day before and the day following, on the day of the convulsions there was a large amount with a great many casts.

Of our 21 non-fatal cases thus diagnosed, the urine was at the upper limit of normal in 18 and was much increased in 3 cases. The increase was at certain periods and alternated with smaller amounts. The specific gravity was not over 1010 in 10 cases. There were traces of albumin at times and periods in which none was found; hyaline and granular casts were also present.

SUPPURATIVE NEPHRITIS.

In these cases we found the ordinary symptoms of acute nephritis with albumin of varying amounts, but only a few casts. In the sediment, however, in one case there were a great many red blood cells and leucocytes. In the other cases these seem to have been very few.

ABSCESS OF THE KIDNEY.

In practically all cases there were microscopically pus cells present, although few in number. The albumin was present in but traces, and was often absent. Either no casts were found, or only a few hyaline and granular present occasionally. The reason may be the same as for the absence of albumin, viz., that for days this kidney may excrete nothing.

TUBERCULOSIS.

In all our cases of tuberculosis of the kidney of which we have notes there was a trace of albumin and a few hyaline and granular casts. On one day in one case there were enormous numbers of casts with a trace of albumin, but later the casts were fewer in number.

CONGENITAL CYSTIC KIDNEY.

The urine in this very rare condition may be normal, or may show the picture of the chronic interstitial nephritis with small, contracted kidney. The amount of urine increases and the specific gravity is low, with

or without a trace of albumin; often blood cells are found. In our two cases the specific gravity was from 1007 to 1013. Albumin was present only as a trace, but terminally even as high as 1 per cent. was found. In one case, in a great many examinations, but one hyaline cast was ever found; in the other case, with 1 per cent. of albumin, no casts were found. Red blood cells and various epithelial cells were quite constant.

CANCER OF THE KIDNEY.

In 4 patients with cancer metastases in the kidney, in 1 without nephritis there was a trace of albumin, and many hyaline and granular and a few waxy casts with renal epithelium. In another case in which the right kidney was practically destroyed the specific gravity of the urine was from 1017 to 1030, a trace of albumin was present on certain days and no casts at any time. In another case, in which the left kidney was practically gone, there were neither casts nor albumin.

"SHOWERS OF CASTS."

Very interesting events are "showers of casts"; by this we mean the sudden and temporary appearance of large numbers of casts in a urine in which before and after few or none had occurred. The albumin may increase or decrease or remain practically the same.

Wagner gave as reason for pure cylindruria that the casts were formed during a transient albuminuria, remained in the tubules, and were later washed out as urinary excretion improved. This would hardly apply to cases in which a long-continued cylindruria is the important feature, and the albuminuria very transitory, but may explain some of these showers of casts which contain none but the varieties formerly present.

They occurred in 34 of our cases with autopsies, and it is interesting that 28 or 85 per cent of these were cases not diagnosed clinically as nephritis since the renal features seemed subordinate.

These cases were nearly all of slight chronic diffuse nephritis, often with scarcely any symptoms, and the sudden increase in casts meant some sudden disturbing element; perhaps a circulatory change, or the elimination of some irritating body.

The best illustration is Külz' sign of oncoming diabetic coma. Suddenly, within twenty-four hours before coma, there appears a quantity of casts in the urine, chiefly finely granular, perhaps unparalleled in clinical experience, which form a huge gross sediment filling the urine glass even one-sixth, and sometimes without albuminuria.

These casts are of characteristic appearance, with a short, broad, delicate outline, pale, and mostly granular and hyaline, with few other formed elements.¹

There are two general varieties of this output of casts: those with the sudden appearance of large numbers of the same kind of cast as was previously present, and due perhaps to the washing out of the tubules. This follows a diuresis, due, for instance, to a salt infusion. Since the casts long in the tubules are often waxy, these may appear for the first time.

The other variety has casts of all sorts present, especially those indicating an acute exacerbation of the existing disease.

These showers of casts are usually terminal events. They may be manifestations of an acute terminal process, with increase in albumin and the other elements of an acute nephritis. This was true in 12 cases, 6 of them

1. Domanskyj and Reimann: *Ztschr. f. Heilk.*, 1901; Herrick: *Amer. Jour. Med. Sci.*, vol. cxx, 1900.

cardiac and arteriosclerotic patients, one a case of liver cirrhosis, and three febrile cases, typhoid, pneumonia and pleurisy, and two of nephritis and uremia.

Or there may be a final increase of the casts only; this was true of 5 cases, 3 of chronic nephritis and arteriosclerosis, 1 a heart case, 1 a case of cancer.

In 6 cases in the terminal shower casts appeared then for the first time, or at least followed a cast-free period; this was true of a case of gout, in which there were small contracted kidneys, two cases of cancer of the stomach, two of tuberculosis and one of arteriosclerosis with cerebral hemorrhage.

The shower may occur during the course of the disease. Then also it may be an acute exacerbation of nephritis, as in three cases, two of arteriosclerosis, one of typhoid fever with suppurative nephritis. In a case of thoracic aneurism and one of tertiary lues, there was only a trace of albumin present.

The cylindruria may introduce an acute process and then diminish as the albumin appears; as in a case of chronic parenchymatous nephritis. Or the albumin may appear even a month later, as in a case of cancer of the stomach.

If the shower follows a diuresis to any cause, as a salt infusion, the casts probably represent the washing out of casts resting in the tubules, and in nature are similar to those previously present. In one of our cases it followed the man's rising from bed.

In three cases no casts were present immediately before nor after. One was a case of multiple renal abscess and two were cardiovascular cases.

In 25 other cases the casts were out of all proportion to the albumin, which was in some cases absent for a time or during the entire stay in the hospital; in others at most there was but a trace. The general conditions were: Typhoid, 1; pneumonia, 3; pyemia, 1; malaria, 1; sarcoma, 2; tuberculosis, 4; endocarditis, 3; dysentery, 1; cardiac disease, 4; cirrhosis of liver, 3; septicemia, 1; cerebral tumor, 1.

The renal condition was: Acute nephritis, 1; acute hemorrhagic nephritis, 2; glomerular nephritis, 1; subacute nephritis with infarcts, 1; fatty kidneys, 5; congestion, 2; cloudy swelling, 3; metastatic abscess of kidney, 1; tuberculosis of kidney, 1. The others were cases of chronic diffuse nephritis; only three of these cases were clinically nephritis.

In 39 of other cases a small amount of albumin was present, but no casts or only an occasional one.

The clinical diagnosis was: Cardiac and arterial sclerosis, 6; cancer of the stomach, 4; thoracic aneurism, 1; tuberculosis, 7; cirrhosis of liver, 2; chronic diffuse nephritis, 3; leprosy, 1; acute peritonitis, 1; acute lobar pneumonia, 6; pernicious anemia, 2; septicemia, 1; congenital cystic kidney, 1; pyelonephritis, 1; typhoid, 2; diabetes mellitus, 1.

The renal diagnosis was: Chronic diffuse nephritis, 24; fatty degeneration, 7; fatty and cloudy degeneration, 1; extreme cloudy swelling, 2; subacute nephritis, 1; acute nephritis, 2; chronic passive congestion, 1; amyloid disease, 1; congenital cystic kidney, 1.

In 19 cases no casts were present and no albumin.

The clinical diagnosis was: Exophthalmic goiter, 1; Hodgkin's disease, 1; tuberculosis, 5; acute lobar pneumonia, 1; lues, 1; colitis, 1; cardiac disease, 2; aeromegaly, 1; cancer of stomach, 1; chronic bronchitis, 1; diabetes mellitus, 1; hemiplegia, 1.

The renal diagnosis was: Fatty kidney, 3; cloudy swelling, 3; chronic diffuse nephritis, 9; waxy kidney, 1; chronic passive congestion, 1; arteriosclerosis, 2.

OCCURRENCE OF CASTS.

In nephritis the epithelial casts occur wherever the process is at all acute, yet they occur in other conditions not nephritis. Their occurrence suggests the statement formerly made, yet often denied, that the renal epithelium is easily desquamated, as is any mucous surface from a slight "catarrhal irritation."

The coarsely granular casts occur especially in a subacute process; never in transitory processes.

Fatty casts occur especially in conditions with fatty degeneration of the epithelium, hence especially in the large white kidney of subacute or chronic nephritis, and in our experience in malarial nephritis. They occur also in phosphorus and arsenic poisoning. These two forms of casts are of greater significance than the epithelial, yet even they may occur in simple chronic passive congestion.

Blood casts occur in large numbers in acute nephritis or acute exacerbation of a chronic nephritis; in considerable numbers in subacute nephritis, perhaps always, while even in the most chronic cases one is apt to find a hyaline cast with a blood cell attached.

Blood casts occur also in conditions not nephritis, as in circulatory changes in the kidney, after the exertion of athletes, and in cloudy swelling. They occur much oftener than they are reported. Fibrin casts are very rare, and if they occur at all it is in intense hemorrhagic processes. Pus casts (cells attached to hyaline casts) practically always may be found in any acute nephritic process. Casts composed entirely of pus cells occur chiefly in suppurative lesions; but leucocyte casts, both pure and combined, are much more numerous than suspected; some of them are called epithelial, and most are not recorded. Slight irritations of the kidney cause the output of leucocytes even more frequently than of hyaline casts, as if the first indication of irritation was pus in the urine, then hyaline casts and with them often casts with cells attached (see Gläser, also Lütke).

Waxy casts may occur in amyloid degeneration of the kidney, but not always, and are not best seen there. They are the rarest form, and occur chiefly in subacute nephritis, anywhere where coarsely granular casts occur, never in transitory conditions. In our 36 cases in which they occurred, all but three were cases of pronounced nephritis, chiefly chronic. The suggestion that these casts occur best after a considerable stasis in the tubules is relieved, that is, that they are only very condensed hyaline casts or granular casts which have undergone this metamorphosis, is borne out by the facts that we have seen the most brilliant pictures in cases after decapsulation of the kidney, also in the urine found in the bladder just at death; also that in sections the casts in closed tubules are waxy.

Finely granular casts occur in all cases of chronic nephritis, and are of much greater importance than hyaline.

The truly hyaline casts occur in any condition in which albumin might be expected, always in nephritis, and in the simplest, most transitory circulatory disturbances. They may be the only cast present in the severest form of nephritis, the chronic interstitial with uremia. No better illustration than this is necessary to show how little can be concluded from the presence of hyaline casts alone.

That great group of casts called hyaline, which resemble slightly the waxy, occurs in all forms of nephritis.

The hyaline casts occur oftenest; they may mean lit-

tle or nothing, but they are the first to appear in a pathologic process, and the only ones in some most serious conditions; therefore they must not be overlooked. If but one form of cast is present, it is always the hyaline; when two, hyaline and finely granular. Hyaline casts are always present when any are. Epithelial, coarsely granular, and fatty may occur one or all, but always with hyalines, although the latter may be rather in the background; the same is to be said for leucocyte and blood casts.

CASTS IN NEPHRITIS.

In nephritis the casts run roughly parallel to the albumin; in acute nephritis there are many, in the severe subacute form most, in the small contracted kidney fewest. In all these conditions it is not the lesion as a whole which controls the cylindruria, but rather more the acute element, hence the urinary picture is often the same in the acute exacerbations of chronic interstitial nephritis as in acute inflammation of an otherwise normal kidney; that is, the process, not the disease. The urinary picture we see in the ward is not as a rule the typical one, especially for the cylindruria of almost normal men. For these, the reports of insurance companies are much more valuable, or those of the examination boards for the Army or Navy.

When the individual is admitted to the hospital it is usually with an exaggeration of the renal condition, hence the condition is more that of an acute process which levels all cases to an almost uniform standard.

In the very acute nephritis one sees many hyaline, granular, epithelial, blood and leucocyte casts. In a case in which improvement is rapid, hyaline and granular casts are found; these diminish rapidly in number, then disappear.

If the case becomes subacute, with a large white kidney and with much degenerated epithelial cells, the hyaline, epithelial and bloody casts continue, but in less numbers, and coarsely granular, fatty and waxy casts appear. Then casts are present in greatest numbers.

If the case goes on to chronic nephritis soon hyaline and finely granular casts will be found in varying numbers, which will diminish as the case becomes still more chronic, till in the urine of a small contracted kidney will be found after long search only a few hyaline casts, and perhaps not these; yet even while few, some blood casts are seen. When the casts are absent, Bard says that the inflammatory process has ceased.

At any time an acute exacerbation may cause the appearance of all the features so far as casts go of an acute nephritis. In amyloid disease few casts are the classic feature.

From one urinary examination alone practically nothing can be learned. All the casts of acute nephritis could be found in the acute exacerbation of a chronic case; and also in conditions which are transitory and leave no scar, as some cases of cloudy swelling, fatty infiltration, and chronic passive congestion showing all the features of acute nephritis. The same is true after severe physical fatigue, as observations on athletes, bicycle riders and foot racers show; also for a few hours after an operation on the kidney.

In the diagnosis of chronic nephritis, "it is not so much the casts, their number or variety which are of as much importance as other urinary features, the specific gravity; e. g., and of greater value than this is the history of the case, and of greatest value the physical examination of the patient, the cardiovascular features, etc." (Osler).

NEPHRITIS WITHOUT CASTS.

In cases of very chronic interstitial nephritis there may be periods in which the urine is cast-free. The acute inflammatory element in the process has now ceased, but with a slight disturbance they will reappear.

In other cases of nephritis it is more probable that the casts have disappeared because of alkalinity of the urine, etc., than that they were not present.

Treutlein² found them constantly absent even in typical nephritis in a case of bacilluria. The *Bacterium coli* in the bladder or pelvis of the kidney can cause their disappearance in these cases.

CYLINDRURIA AND NUCLEOALBUMINURIA.

Kossler tried to establish this combination as distinct from albuminuria and cylindruria. These complexes may alternate or the former may precede or succeed the latter. It was present in his cases of "pure cylindruria," in six of which at autopsy only degenerative changes of the epithelium were found, cloudy swelling, fatty degeneration, even necrosis, but no signs of active inflammation. The nucleoalbuminuria and cylindruria of especially epithelial casts occur so parallel that they may be connected; and this might be expected, since nucleoalbumin many think is derived from degenerating cells, and the list of occurrences of nucleoalbumin are those of pure cylindruria as well.

PURE CYLINDRURIA.

To say that there are cases which, from the first, are pure cylindruria, is absurd, since clinical experience shows how temporary is the albuminuria which sometimes is followed by cylindruria; also the wide difference of opinion as to what constitutes a trace of albumin explains many cases.

Among the more acute cases may be mentioned that one reported by Müller in his study of bicycle racers, in which there were many casts, hyaline, granular and epithelial. Cases of pure cylindruria occur in cases of evidently slight irritation of the kidneys, due to foods as asparagus, radishes; to coffee, mustard; to certain drugs, as alcohol, salicylic acid; in certain diseases, especially valvular heart disease, arterio-sclerosis, cancer, certain diseases of the nervous system, inflammatory diseases, acute infections. In these cases the casts are hyaline and granular, but also epithelial.

The observations made by Gläser³ under v. Jaksch's directions are especially interesting. Normal persons from 20 to 30 years of age and not accustomed to much alcohol, and whose urine had been proved normal were given varying but considerable amounts of beer and the centrifugized urine examined when very fresh. Of 106 persons, the leucocytes were increased in 33, and casts were present in 25. Uric acid and calcium oxalate crystals were other manifestations of the irritation of the kidney by the alcohol. No albumin (careful tests made) was present in any case. In only 6 cases was no effect at all evident.

Of the 25 persons with casts, hyaline and leucocyte casts especially were found in 9. In 7 the casts were hyaline, with a few leucocytes attached; in 2 the casts were agglomerations of leucocytes. Epithelial casts were present in 9, in 8 mixed epithelial and hyaline were present, and in 1 pure epithelial casts. A few fatty casts were found. The effect lasted about thirty-six hours. In severer cases albumin was also present.

Lüthje⁴ found that medical doses of sodium salicylate always affected the kidneys. Thirty-three individuals were examined. The administration of this drug was followed always by the presence of casts and cylindrurids, leucocytes, often albumin and often epithelial and red blood cells. The effect lasted from fourteen to twenty-one days. Of 204 urine examinations made in 33 cases, in all casts were found and 96 in albumin also. Sometimes with no albumin were many casts. The casts were more especially hyaline and granular, a few leucocytes and epithelial casts were found, never any waxy casts. He thinks the condition a genuine nephritis.

Türk found pure cylindruria after administration of camphor, arsenic, mercury and tuberculin.

Casts alone are more suspicious of nephritis than is albumin alone, but in both cases it is the chronicity of their presence which is of greatest importance.

The presence of casts without albumin in nephritis is not rare if one centrifugalize the urine well.

For the past two years we have paid this point particular attention and examined all in the hospital in which this condition was present, and we find that in many cases of transient albuminuria the cylindruria will outlast the albuminuria. This is particularly true in those cases of chronic nephritis to be attributed to a parenchymatous lesion, that is, a case previously acute. In those cases of arteriosclerosis, that is, the degenerative type, we find that the reverse is more common. In cylindruria not due to nephritis the casts are rare and those found are hyaline as a rule.

In chronic interstitial nephritis there are often long periods of pure cylindruria, but the casts very scarce indeed, and chiefly hyaline, perhaps with a few finely granular. Such are the cases originally reported by Mahomet, Millard, Purdy and Gull, cases of arteriosclerotic kidneys "arteriocapillary fibroid nephritis."

A pure cylindruria sometimes occurs instead of an albuminuria under the conditions usually termed physiologic.

Stewart⁵ reports a group of six or more cases of a type of nephritis which he thinks wholly distinct from the chronic interstitial form. These cases have the symptoms of marked renal insufficiency. He thinks albumin never is present, but casts always, hyaline casts especially, rarely granular, epithelial in two cases, and waxy casts in one case. The cases have not been examined as yet anatomically.

In 3 of 19 cases of erysipelas casts without albumin were found. In 33 per cent. of these cases casts or albumin, or both, were present (Pollatschek⁶). There were in one case albuminuria and casts during the six days of fever, and then pure cylindruria during the succeeding six. The other two cases presented few casts, no albumin.

In cases of eclampsia, casts alone may be present after a very slight transitory albuminuria has disappeared. Tonelli⁷ reports such a case in which a woman twelve days after delivery went into sudden coma; a trace of albumin was present, then none; but very many casts, especially hyaline and granular, persisted until recovery. It is claimed that as a rule the reverse is true. Friedenberg⁸ in 51 cases of postpartum albuminuria found casts in but 3. In tuberculosis pure cylindruria is not rare. Craandijk found it in 10 of 109 cases. The casts were

especially hyaline, about a quarter of them granular, a few showed leucocytes and degenerated epithelial cells attached, and in about one-half the cases a few red blood cells were present as well. Kossler⁹ found pure cylindruria in 18 cases of chronic tuberculosis, especially those late in the disease with evident cavity formation and a long period of hectic fever. Some at the end had cachectic edema, none symptoms of amyloid disease. The casts were few or very many and of all forms; especially hyaline and granular, almost always a few epithelial; most hyalines had these cells attached, but there were also pure epithelial casts; there were some coarsely granular casts, also some pus casts, on one or two occasions waxy casts, and in some blood casts were present during a long time even in large numbers, some of them pure; in other cases red cells were attached to hyaline casts. Cylindrurids were also present. In some cases the cylindruria was very transitory.

In cases of endocarditis sometimes pure cylindruria is found.

Cylindruria accompanies constipation and diseases causing this (confirmed in animal experiments by Wallerstein). Koller reported two such cases of chronic constipation, two of acute constipation and one of appendicitis. He considers the cause a reflex one causing vasomotor disturbance, hence nutritional disturbance of the epithelium. In other such cases the cylindruria outlasts the albumin. The same is true of various inflammatory troubles of the intestine.

One of the first illustrations given was jaundice due to any cause, which was accompanied in every intense case by albuminuria and cylindruria, or the latter alone. Nothnagel found casts always and albumin in but one-third of the cases. In diabetic coma pure cylindruria may occur.

Pure cylindruria occurs in a group of cases in which circulatory changes seem the only common element, as in valvular heart disease and arteriosclerosis, but more often with such cases is pure albuminuria.

CASTS IN NON-NEPHRITIC PROCESSES.

By non-nephritic is here meant a very temporary condition lasting but a few days or hours and with no sequelæ. The condition, of course, often may be a true nephritis.

In our cases of chronic passive congestion with autopsy, hyaline, granular, epithelial, waxy, fatty and pus casts: all gradations from a few hyalines to the picture of acute nephritis, were found; in acute congestion granular casts were found. In cloudy swelling, hyaline, granular, blood, epithelial and waxy casts were seen. In fatty kidneys, hyaline and granular casts were found. Febrile albuminuria is practically always also cylindruria. These accompany jaundice as long as it lasts: diabetes, anemia, and after the ingestion of many irritating foods. Very temporary disturbances of the kidney may present the picture of acute nephritis. These symptoms are present, with a trace of albumin, in about 50 per cent. of cases of general anesthesia for from twenty-four to forty-eight hours. Brown¹⁰ has described some interesting cases of operations on the kidney, the urine previously normal; the operations were nephropexy or exploratory nephrotomy. On the first day following the operation, casts were present in enormous numbers. There were hyaline or granular, blood or epithelial. The field was simply crowded with them. Considerable albu-

min was occasionally present. They diminished rapidly in number and in a few days (from two to six) had entirely disappeared. During this time there had been no symptoms of nephritis, no edema and the amount of urine was normal. The most striking feature was the disproportion between the amount of albumin and the number of casts, this being greatly in favor of the latter. There were no later symptoms.

Another very good example is eclampsia, in which the cylindruria and albuminuria are extreme, yet at autopsy (after death due to hemorrhage) the kidneys may be found apparently normal.

The postural orthostatic physiologic albuminuria is practically always accompanied by casts, if one take the trouble to search. Casts occur with albumin after the massage given the kidneys by bimanual palpation. Derrington, in the urine of the oarsmen of the Harvard crew, found casts common. After a bicycle race, Müller, in the urine of 8 trained men, found in 7 albumin and casts and in 6 very many casts (these 6 including the albumin-free case). The casts were hyaline, granular and epithelial. They were gone the next day. In another group of twelve, casts were found in seven.

CASTS IN THE URINE OF NORMAL MEN.

That casts could be found in the urine of normal men has been believed by the earlier observers from the time of Hentle. The finer changes in the kidney in nephritis were not then well understood, and examinations, such as made by insurance companies, were not practiced, hence these men may not have been strictly normal. Again, at that time, cylindroids were counted as casts, perhaps rightly.

As Osler has emphasized, it is rare to find a normal kidney in a man of over 50 years of age. The high strung, rapid life often shows its effect first on the kidneys and a slight increase of connective tissue, and some atrophied and sclerotic glomeruli are found. The process of senile atrophy alone, however, causes no albumin or casts, although half the renal tissue may have disappeared. It is the inflamed degenerated condition of the still-functioning epithelium.

The statement has not recently been made that casts occur in the case of normal men, and all such are considered as poor risks by insurance companies.

MEANING OF CASTS.

Casts occur wherever albumin might or does occur, but although usually associated, either one may be present without the other. It is safe to say that it is the renal cells which are at fault.

The lesion causing cylindruria may be very slight, very trivial, very temporary—some slight temporary disturbance in renal circulation; malnutrition of the cells, anemia due to any cause; the excretion of any irritating substance. Renal cells are some of the most sensitive in the body. Many think that a few hyaline casts means nothing but the most observers agree that any number, even of hyaline casts, means an irritated condition of the renal cells.

The cast may be a good index of the present state of the cell, whether merely irritated or totally destroyed, but gives absolutely no clue to the process behind that condition of the cell, whether a temporary malnutrition or an acute nephritis or a chronic nephritis with almost entire destruction of the kidney and with impending uremia. In fact, it seems as if the cells of a normal kidney could give a more vigorous demonstration of their disturbed condition by a more brilliant output of casts

than could those of a diseased kidney. The latter seem to become accustomed to their condition and form even no casts.

To say that casts and albumin run roughly parallel is hardly correct, since one must distinguish between formation and elimination of casts, perhaps between elimination of the materials for casts and their formation.

Casts, however, are of much importance in following a case of nephritis or other renal disturbance.

For them to be present temporarily and then to disappear entirely means, no matter how alarming their number and variety may have been, a temporary and probably harmless disturbance; for them to continue for days, weeks, or months, no matter how few and how insignificant the onset of the trouble, means chronic nephritis; and for them to remain two years means, it is said, an incurable case.

In a case of nephritis, for the number to diminish and to include hyaline and finely granular casts means a subsidence of the acute process, while the reappearance of the epithelial, coarsely granular and bloody casts means a flare up.

That they precede albumin in certain early cases of nephritis remains to be proved. In scarlet fever, the casts may outlast the albumin, which ceases with the temperature, but in some cases from the first there seems to be only cylindruria, and this ceases with the temperature. In typhoid fever pure cylindruria is not at all rare and especially that following an albuminuria. The casts may even become more numerous after the albumin stops.

Phosphorus poisoning may produce only casts, and these in abundance, epithelial with the cells at all stages of fatty degeneration, and fatty casts. Casts also occur in acute infections of various sorts, in the cachexia due to cancer, etc., in diseases of the central nervous system, in various lung diseases, as pneumonia and severe bronchitis, in which blood casts may be the prevalent form, and in empyema.

CONCLUSION.

In the preceding pages we have given the experience of this clinic in the field of urinary diagnosis. The microscopic examination of the urine is indispensable, yet only as an aid to physical examination of the patient, for the examination of one specimen of urine will seldom be enough for a diagnosis.

In conclusion, we wish to emphasize the fact that casts alone are no index of the anatomic renal condition. Their most brilliant display is in non-nephritic condition; the most serious conditions in nephritis may be accompanied by few or none.

The more normal the cells the better do they seem to form casts when disturbed; in chronic conditions the cells seem to become accustomed to their condition and to form few casts or none.

The duration of the occurrence of casts is of great importance, and a given case may be well followed by the casts. Epithelial, blood and pus casts are more common and of less significance than is usually supposed.

DISCUSSION

ON THE SYMPOSIUM ON NEPHRITIS.*

DR. JOHN A. WITHERSPOON, Nashville, said that for a number of years he has been very much impressed with the reparative and recuperative powers of the kidneys. It has been taught, he said, that the kidneys have but little reparative or recuperative powers and yet many physicians have witnessed the disappearance or subsidence of conditions at the

* Part of this symposium appeared in THE JOURNAL last week.

bedside, and of the pathologic findings. Everything must be taken into consideration before the physician makes a positive statement, or gives a positive diagnosis. No man can depend on the clinical findings alone at the bedside. The successful man will have to rely in all his cases largely on what he finds by a comprehensive view of the entire situation. In no character of cases is this more necessary than in the consideration of kidney lesions. Dr. Witherspoon has been impressed with the fact that many men are in too big a hurry and rush through their diagnosis too rapidly. In kidney cases above all the quantity of the urine in the twenty-four hours, with repeated test microscopically and chemically of the urine in many cases will make a diagnosis. One can not jump at conclusions as is often done by the simple finding of albumin and casts. The rapidity with which some men make their diagnoses is to be censured, he said. More time should be taken in the examination of these patients. Many cases diagnosed as Bright's disease are not really that disease at all. Many prognoses would be changed if the cases were watched a sufficient length of time. In the management of the cases one should be able to recognize the danger signals even when the patient is apparently getting along comfortably. The process may be an insidious one or a stormy one, but there are certain things that should serve as danger signals, such as the uremia and evidences of cardiac changes. The heart is responsible for many of the troubles that arise with broken compensation, or when the hypertrophied left ventricle gives away. If the physician early recognized these danger signals, such as twitching of the muscles, or irregular or dilated pupils, or changes in the quality or quantity of the urine and other signs he would be able to prevent many of the subsequent dangers. Dr. Witherspoon said that medicine plays but a small part in the treatment of disease, and less in the treatment of kidney disease than in any other. In these cases success will depend chiefly on regulation of diet and on the general management.

He believes that many men have been much weakened in their vital resistance and in their muscular powers by improper dieting, resulting in malnutrition, especially such dieting as was prevalent years ago. It is horrible to contemplate. Many of these patients with chronic nephritis may live for years if they are not scared to death. He cautioned against allowing the patient to pay more attention to the taking of medicines than to the sanitary surroundings. He has had patients say to him: "I have missed taking a dose of your medicine," and he really wished that they had.

Dr. W. Ostrits, San Francisco, stated that at the pathological laboratory of Cooper Medical College, he and his assistant have been interested in studying the relation between albuminuria and nephritis and his assistant, Dr. Wm. Osmer, has carried on a long series of investigations of the urines as a routine measure in autopsies. With the findings in the urine and the actual microscopic condition of the kidneys noted, they were compared. The investigation brought out very much the same facts as mentioned by Dr. Emerson. Their experience, Dr. Ophüls said, certainly shows that even a large amount of albumin and casts of any kind may be present in the urine and still, besides chronic passive congestion, no lesions can be recognized at autopsy, either with the naked eye or with the microscope. That is to say, in a large number of the cases the urine showed a considerable amount of albumin and casts in large numbers and all varieties, without inflammatory lesions in the kidney to account for them. This plainly shows what a difficult matter it is to distinguish between the last stages of heart disease and the last stages of kidney disease from an examination of the urine alone. They also found how difficult it sometimes is to recognize even acute kidney lesions by an examination of the urine. In chronic cases urinary analysis often revealed very little, especially in instances where but one examination was made; so that from the pathologic side it must be emphasized that an examination of the urine alone either once or when done repeatedly is not sufficient to make a proper or conclusive diagnosis of the existing conditions. So far as classifying the various types of the disease is concerned Dr. Ophüls agreed with Dr. Shattuck that physicians

must adhere after all to an anatomic classification. As to just what this classification should be he is as yet in doubt. He is sure, however, that it should be based not so much on the minute histologic details but on the grosser features of the disease. A very good sign of what we may be coming to is shown by the report from the Johns Hopkins Hospital, showing that they are attempting to classify their cases of nephritis according to anatomic lesions; they have returned to the oldest anatomic classification, that we possess distinguishing between the large white kidney and the small red one.

Dr. L. DUNCAN BULKLEY, New York, related his own case. In 1869 he had a very severe attack of acute nephritis. He was attacked suddenly and the urine became as black as coffee, thick and solid. He was sick a number of months and was compelled to give up his hospital work. He went to the country. Since then he has had three or four acute attacks, the most severe being eight or ten years ago, when going through the Yellowstone Park. Then the urine was black as coffee, thick and solid. For a few days he took absolutely nothing but milk and then he went to Vancouver and dieted more or less. The plan of treatment he advocates is the taking of pure warmed milk, perhaps a little diluted, one or two hours before eating. He never takes milk with his meals. From that time to this, i. e., for twenty-five years or more, during six days in the week, he consumes a quart of milk a day and takes a moderately fair diet. One goblet of milk is taken at 12:30 and three goblets after 11:30 at night. The milk should be taken between meals and at the temperature of the body so that it can be absorbed immediately and pass into the lacteals, etc. When Dr. Lambert examined Dr. Bulkley for insurance, he said that he would live fifteen years; that time has expired some time ago. Dr. Bulkley has been refused several times by life insurance companies because of the presence of so much albumin in the urine. He has had several policies granted him, however, because before going for examination he has been careful for a few days or weeks. He believes that it is of immense importance to know just what the kidneys are doing day by day, and week by week. He has a number of patients whose urines are tested day by day. He has the entire quantity of urine passed in the day examined in order that he may know the absolute quantity in ounces that is passed and which enables him to mark out the coefficient of the solid ingredients, a thing which he considers to be of more importance than knowing exactly the exact quantity of albumin. One should know exactly whether or not the patient is passing from the body in twenty-four hours his equivalent of solids.

Dr. G. V. McCASKEY, Fort Wayne, Ind., said that he thinks that those who have given the dietetic treatment of chronic nephritis careful attention are almost a unit in regard to the necessity of properly feeding these patients. Several years ago he became especially impressed with the fact that they were underfed. Patients went to him emaciated and weak from the long continued use of toast and slop diets. He then began cautiously to experiment with more substantial diets, gradually introducing liberal quantities of meat. The effects on albumin excretion, casts and the general symptomatology of the case was carefully observed, and these patients were found not only not to do worse, but to do better in every respect. It is not the color of the meat which is the proper criterion, but its digestibility. No general rules can be laid down with regard to the absolute quantity of meat to be given, but he has been in the habit of making a sort of test by giving such a patient a full meal of meat; and if the urea output goes up sharply, it proves to his satisfaction the existence of such a degree of renal capacity as will justify such a diet. He referred to the importance of paying especial attention to the gastrointestinal tract. He thinks it is not saying too much to affirm that in a large proportion of the cases of chronic nephritis, the disease is caused by toxins absorbed from the gastrointestinal tract. The therapeutic importance of this fact is obvious. In many cases the stomach and intestines should be carefully investigated by chemical and microscopic methods, and in many

the patient will be greatly benefited by suitable local treatment of the morbid conditions thus revealed. With regard to Dr. Brown's paper Dr. McCaskey does not feel convinced from the data he presents that the kidneys are not at fault in the causation of clamtanic seizures. Of course, there are many other factors, but the increased toxicity of the blood is best explained by inadequate renal function, assuming, of course, the increased formation of toxins. This does not necessarily mean organic renal disease, for the real trouble may be cardiac or vasomotor. Dr. Emerson said that in the degenerative lesions of chronic renal disease the albumin persists longer than the casts. His conclusions are based on an extensive series of cases in hospital practice. Now, if they are to be accepted, it seems to Dr. McCaskey that a logical inference is that albuminuria is a more important indication of degenerative renal disease than the presence of casts.

Of the tests for albumin, he prefers the use of the Janet reagent as the initial routine test in all cases. The formula for this is: Hydrazine, bichloride, 1.35 gms.; potassium iodid, 3.32 gms.; acid acetic, 20.00 c.c.; aque, 64.00 c.c. All forms of proteins respond to this test, and can be excluded at once if a negative result is obtained. If the result is positive, then other tests such as those described by Dr. Stengel can be used to determine its clinical significance. Dr. McCaskey referred to the statement in the abstract of Dr. Councilman's paper, printed in the program: "Interstitial changes in the kidney are secondary to injury of the parenchyma." He said that this statement should not pass without comment, because it tends to convey an impression which the author certainly does not intend, that interstitial nephritis is usually the result of the parenchymatous form which is not in accordance with the facts.

Dr. WOODS HUTCHINSON, Portland, Ore., said that the thing we most need to-day is to get a clear conception of the fact that Bright's disease is not primarily a disease of the kidney; its causes exist outside of that organ. In many cases the kidney trouble is the localized result of a general arteriosclerosis or fibrosis, and this is usually due to the presence of toxins in the blood. We can more and more trace this as a cause of nephritis and we are less and less over-looking influenzas, summer diarrheas, ptomain-poisonings, etc., as causes. Whenever there is this toxic condition the kidneys suffer chiefly from their attempt to eliminate. He believes that the importance of albumin and casts has been greatly exaggerated. Really the amount of albumin found in the urine is an unimportant consideration. It is never a symptom of inflammation and the important question is, what is the cause of this intoxication? He believes that food has very little to do with its production and yet we have taken milk as the food in Bright's disease. Milk is an admirable food, blameless and innocent, both in the color and in its association with childhood days, yet he believes it is dangerous in nephritis because of the heavy percentage of work that is thrown on the kidneys, as von Noorden has shown, in proportion to its nutritive content, more so than by any other food. It also swarms with bacteria. In milk shakes, and milk punches the real danger is often from the milk rather than from the alcohol. Although red meat has both the color and attractiveness of sin, yet its actual nutritive value is probably more than that of any other food in proportion to the work it throws on the kidneys. With regard to any diet this must be remembered. The kidneys are there for their own benefit, as well as for ours. What we call excretion or elimination they call feeding. A nitrogenous diet is necessary for the proper nutrition of the kidney cells, and we lower their vitality, as well as that of the body generally, when we cut it off or reduce too low. Any diet that diminishes the amount of fermentation in the intestines of the patient and builds up his strength is the diet that is best fitted in cases of nephritis, regardless of whether it be proteins or carbohydrates, alcohol or milk.

Dr. A. P. FRANCINE, Philadelphia, referred briefly to work being done by Dr. Joseph Walsh of the Phipps Institute of Philadelphia, in reference to nephritis occurring in those dying of pulmonary tuberculosis. In all 53 cases have been ex-

amined, both macroscopically and microscopically. The kidneys were sectioned as usual, described and then further cut up. Anything abnormal found was blocked and studied microscopically. From twelve to one hundred microscopic specimens were studied in every case. Frequent and accurate examinations of the urine were also carried on from the time the patients entered the wards. Often the urine analysis was negative, while the kidneys showed a pathologic nephritis. The findings are mainly pathologic. He referred to the more important facts. The following is a tabulated list of results: Normal, 1; congestion, no tubercles, 3; cloudy swelling, scattered tubercles, 1; toxic nephritis, no tubercles, 4; toxic nephritis, scattered tubercles, 10; parenchymatous nephritis, no tubercles, 7; parenchymatous nephritis, scattered tubercles, 8; interstitial nephritis, no tubercles, 1; interstitial nephritis, scattered tubercles, 4; diffuse nephritis, no tubercles, 2; diffuse nephritis, scattered tubercles, 6; cloudy swelling, scattered tubercles, amyloid degeneration, 1; parenchymatous nephritis, scattered tubercles, amyloid degeneration, 1; ulcerative tuberculosis of kidneys (surgical kidneys), 2; scattered tubercles, 1. Thus 34 of the cases show typical tubercles. From the above results of careful examination it may be seen that nephritis in tuberculosis is common. This occurs usually in the form of parenchymatous or toxic nephritis, though other forms are not infrequent. Normal kidneys in connection with tuberculosis are rare. Glomerulo-nephritis or hemorrhagic nephritis was never found. Tubercles were diagnosed as such, only when they showed caseation and giant cells. Thus of the above series 64 per cent., or nearly two-thirds of the cases, showed miliary tubercles. This is a new and important discovery.

Dr. JAMES J. WALSH, New York, said that physicians succeed in doing something for their patients just in proportion to their early recognition of disease and the use of curative and prophylactic measures, to prevent its further progress. The reason why in recent years the death rate from tuberculosis has been so greatly reduced, is that physicians have learned to recognize the very earliest stages of the disease. Many of the patients who are now sent to sanatoria, a few years ago would have been pronounced by most physicians to have nothing serious the matter with them, so slight are the signs of tuberculosis. Indeed, at the present time, the cry of the specialist in tuberculosis is that more patients are not saved, because the family practitioner has not learned to value at their full significance the earliest signs of the affection. The same thing is true with regard to most of the diseases which the medical man has learned to turn over in recent years to the surgeon. It is because appendicitis can be recognized before it produces general peritonitis, and because gallstones and ulcers of the stomach are considered as worthy of early surgery, that the death rate from these diseases is reduced. If nephritis which has come in recent times to occupy something of the place that tuberculosis held a generation ago, could be recognized during its early stages, then undoubtedly the cure, or at least the prolongation of life with this disease, could be secured as it is in tuberculosis. The kidney symptoms of nephritis are by no means the first to manifest themselves. The urinary symptoms are only manifestations of a local change in the kidney, which has been evident, however, by symptoms from other parts of the body for some time before. It is these early symptoms of constitutional affection, that will eventually lead to the severer forms of nephritis that physicians must try to recognize. There are undoubtedly some clinical symptoms of these earlier manifestations. When the toxins that are eventually to work serious damage on the kidneys are originally absorbed from the digestive tract, they produce only a high tension pulse and a tendency to the disturbance of the heart action. This high tension pulse can be observed in the arteries, and the subjective symptoms of it a fluttering heart with a tendency to the heart beats making themselves felt during a good portion of the day, and especially during severe exertion, not infrequently bring patients to physicians before there are any urinary manifestations or at a time when the symptoms in the urine are so slight as scarcely to attract attention. There seems to

be no doubt that much of the nephritis that is seen is due to the fermentative disturbances in the intestinal tract, which disturb digestive processes. Constipation has become such a common ailment in modern times that a medical wag said not long ago that perhaps it is leading and light that our people need, but it seems more probable that laxative and licorice powder are about what they want. As the result of these intestinal disturbances, a certain amount of toxemia is not at all unusual and whenever there are symptoms that seem to point to disturbance of arterial tension and of heart action, in connection with it, the question of prophylactic treatment so as to prevent the development of nephritis should always be considered. Here is where the only hope in the medical treatment of Bright's disease seems to lie.

Dr. FRANK BILLINGS, Chicago, said that our conception of nephritis may be compared with affections of other end organs of the body, especially the eye and brain. We know that the eye may be affected by local conditions or because of some general bodily defect; thus vision may be disturbed through local disease of the eye, which does not depend on any systemic condition. Vision may be disturbed through local conditions of the eye which are due to some systemic condition, and again vision may be disturbed without a disease of the eye, but because of some systemic diseases, a brain condition. If one should attempt to treat the loss of vision without a diagnosis of the causes of the disturbance, it would be irrational. So of the kidney, another end organ may be diseased locally by inflammation or degenerative changes which are manifested by albumin and casts in the urine, without any systemic disturbances. The seriousness of the condition would then depend on the degree of kidney disease. The kidney may be involved in a systemic disease as a secondary process or as a part of the general disease. The kidney may be much or little affected, the seriousness of the condition often depends on the cardiovascular status. A general disease may exist with cardiovascular changes in which the kidney may be little or not at all involved, as is evidenced by a urine that is practically free from albumin and casts and yet the individual may be as thoroughly a subject of Bright's disease as if the urine contained albumin and casts. It is the failure to recognize the diseased conditions of other organs of the body when there may be evidences of disease of the kidney, as evinced by the presence of albumin and casts, that has resulted in an uncertainty as to the management of kidney disease. Drugs may be indicated in certain of these conditions and the food indicated may be entirely different in each of the conditions named above. He said that physicians generally must agree with Dr. Shattuck in his ideas of diet in Bright's disease.

Dr. JOHN H. MUSSER, Philadelphia, emphasized especially what had been said regarding the classification of nephritis, and the forms of Bright's disease. He also called attention to the importance of making a complete chemical analysis of the urine, a physiologic study, in order to lay down proper lines of dietetic management, as a study of the nitrogen output, and a study of the elements found that are secondary to putrefactive changes in the intestinal tract. The important statements made by Dr. Emerson, he said, should give rise to much reflection, and especially the statement regarding "showers." In one or two instances after the use of salt solution, in cases of interstitial nephritis, Dr. Musser had an opportunity of seeing these extraordinary showers occur. Physicians should not make a final diagnosis in obscure cases of alleged Bright's disease unless the patients are in bed a certain length of time, and the urine examined under such conditions, as well as after exercise and perhaps after various modifications of diet. Finally, he questioned the conclusions that have been drawn from an examination of the urine taken after death. At this agonal period changes occur in all secretions, even though there is no pathologic basis for them.

Dr. M. H. FUSSELL, Philadelphia, sounded a note of warning. He said that it is unquestionably true that the presence of albumin and casts in cases of arteriosclerosis is

simply a part of the general arteriosclerosis, and it is perfectly right that it should be so recognized. It is equally true that albumin and casts in large quantities may occur in many conditions without there being a true nephritis. If it is shown that albumin and casts occurring in the urine does not mean a nephritis, he is afraid that many general practitioners of medicine will say, "Why examine the urine at all?" It is of the greatest importance that albumin be looked for in a routine manner in much the same way as the heart, lungs and arteries are examined in every case. The presence of albumin and casts does not mean necessarily the presence of a nephritis, but they are danger signals, and if we do not examine the urine carefully, we will not be aware of their presence.

Dr. L. LEROY, Nashville, said that while there is a possibility of giving too much attention, or of placing too much confidence in, urinary examinations, still the present tendency to disparage their value is not in keeping with the highest and best work, and the general practitioner is liable to go to extremes and to disregard these findings. Dr. Leroy believes that it is rather a step backward and not a step forward. The finding of albumin and casts does not necessarily mean that the kidneys are not diseased, nor does it mean that they are. He thinks that the future classification of nephritis will be, as Dr. Billings has suggested, not on the microscopic findings, nor so much on the gross anatomic appearances, as on the etiology. Arriving at a prognosis in the presence of relatively small amounts of albumin and casts is one of the most difficult things and this may be a possible explanation of the work Dr. Leroy has been doing during the past two years in examining portions of the kidneys. Frequently he has found a large percentage of the kidney in good condition, whereas certain of the pyramids were in an advanced stage of degeneration. Yet there was sufficient kidney not involved to carry on the work fairly well. With regard to the treatment by diet he has found that the use of boiled meats gives the best results. Boiled meat approximately has as much nutritive value as the unboiled and the process of boiling gets rid of the extractives which are more irritating than useful.

Dr. J. A. LICHTY, Pittsburg, Pa., said that it seems to him that we are coming to the turning of the way. We must look in a different direction for the basis of a diagnosis. Physicians should hold to what they have already gained during the past years and add to that some information which might come by a study of blood pressure. He is surprised that the study of blood pressure has not been taken up in this discussion. The sphygmomanometer will yield information in many cases in which the examination of the urine appears to be misleading. He mentioned two cases which he saw recently. One patient was a man 60 years old, who was thrown from a street car and sustained considerable shock, and did not recover as rapidly as Dr. Lichty thought he should. The urine appeared normal. On taking the blood pressure it was 210 and that aroused suspicions that there was more than the results of the accident to contend with. About the same time a pregnant woman consulted Dr. Lichty. Her urine contained casts and an abundance of albumin. The man had a high blood pressure, but no albumin or casts, and he grew gradually worse, and thirty or thirty-five days later he had convulsions and died. Here was an instance of a man having a nephritis and yet no albumin or casts. The woman had a blood pressure of only 110, with an abundance of albumin and casts, and went through her confinement without any suspicious symptoms; after her labor the urine was perfectly clear and she was perfectly well. These two cases show very definitely the value of the sphygmomanometer in the diagnosis of nephritis or Bright's disease. The direction of study now, Dr. Lichty believes, should be more toward blood pressure and probably the infections.

Dr. ALFRED STENDEL, Philadelphia, declared that the matter of classification of nephritis has been discussed time and again, and it is apparent that no classification can be offered which will prove satisfactory from all points of view. Such working classifications as may satisfy the clinician are inadequate in a pathologic sense. He has considered only acute and

chronic nephritis (parenchymatous) and amyloid disease of the kidney, and has set apart chronic interstitial nephritis as a different sort of process. It is very important that physicians should distinguish parenchymatous disease of the kidney or ordinary Bright's disease, whether acute or chronic, from chronic interstitial nephritis. In parenchymatous Bright's disease there is a disorder of renal function which shows itself in disturbed general metabolism and disordered nutrition of varied type. For a long time at least the condition is essentially a renal affair. On the other hand, chronic interstitial nephritis usually is only secondarily and even in a terminal sense a renal condition; primarily, it is a more or less subsidiary part of the general condition, arteriosclerosis. Dr. Councilman and others have established the frequency of acute interstitial nephritis in certain infections, and reasoning from analogy one may assume that chronic interstitial nephritis might result from such a condition without the necessary existence of general arteriosclerosis. As a matter of record, however, Dr. Stengel has seen very few instances of chronic interstitial nephritis without antecedent arteriosclerosis. According to his view, chronic interstitial nephritis is for practical purposes simply a renal phase of generalized arteriosclerosis, just as in other cases one may meet with a cerebral type. It is important to recognize this because the untoward results of renal inadequacy are far distant and unlikely events in chronic interstitial nephritis as compared with the parenchymatous forms, and for this reason a differentiation must be made. He said that he thinks that Dr. McCaskey misunderstood Dr. Councilman's meaning in the abstract where he states that "interstitial change in the kidney is secondary to injury of the parenchyma." It is a dogma in pathology that all fibroid or interstitial processes have antecedent changes or degenerations in the parenchyma of the organ. There must be cellular destruction before the interstitial processes arise. Dr. Councilman's thought was this, Dr. Stengel takes it, and not what he presumes Dr. McCaskey believes, that all cases of chronic interstitial nephritis are secondary to what we recognize as chronic parenchymatous nephritis. The statement was to be interpreted in an anatomic and histologic sense rather than in this clinical way. Referring to the danger of entire frankness in the matter of pointing out the significance of albumin or of casts in the urine, he agreed that it would be deplorable if practitioners ceased to make routine examinations of the urine, because we here freely acknowledge the deceptiveness of such examinations in certain cases. So far as his own contribution to the subject is concerned he said that there is no difficulty in recognizing established nephritis when one makes repeated examinations of the urine. It is difficult, however, in cases of trivial albuminuria to assert positively whether there is a beginning Bright's disease or some transient condition. Also, it is difficult to assert with positiveness the pathologic significance of albumin and casts in the last days of life, especially when death is brought on by cardiac disease. Repeated examinations are necessary and a study of the case for a considerable period of time enables the physician to reach definite conclusions in all renal cases. Only the routine examination of the urine will lead to a proper understanding of such cases; without it the physician falls into superficial methods of diagnosis.

DR. PHILIP KING BROWN, San Francisco, said that there is no evidence at all to show that there is any intoxication due to the retention of normal end products except in cases of jaundice. He thinks that all investigators have shown that no end products, or intermediary products, have anything to do with the intoxication of eclampsia. None of these products has been found to be uniformly increased in the blood of eclamptic patients, nor has experimental injection of an excess of these products reproduced clinically or pathologically the condition of eclampsia. He said that he wished to correct the impression which Dr. McCaskey has, that the cases cited in which the urea was so strikingly diminished, were cases of eclampsia. They were cases of pathologic conditions of the kidneys or cases in which eclampsia had been present before, but the pregnancies during which observations were made were normal.

CANALIZATION OF THE SIGMOID, THE LATERAL AND A PORTION OF THE SUPERIOR LONGITUDINAL SINUSES FOR MASTOIDITIS

OF TWENTY-ONE YEARS' STANDING, WITH SUBSEQUENT RE-ESTABLISHMENT OF A TEMPORO-MANDIBULAR JOINT.*

BAYARD HOLMES, M.D.
CHICAGO.

INTRODUCTION.

The following case of long-standing middle ear disease, with mastoiditis, sinus thrombosis and metastatic infection in distant parts of the body, is presented as a horrible example. It occurs to me that poulticing a felon, starving a patient with appendicitis, and neglecting a mastoidectomy in antral disease represent the same stage of irrational, cowardly or villainous treatment. When we consider the number who lose their lives, the number who are crippled in hearing, and thus deprived of the advantages of social happiness and education, and, last of all, those who are partially invalidated by the frequent exacerbations of the disease and its general toxemia, the indications for a prompt, adequate and effective mastoid operation become imperative. This patient has met with more of the mechanical and less of the intellectual and social ravages of this disease than many others in my experience. No criticism of the early treatment of this case is contemplated, but I would insist that a similar treatment to-day could hardly receive professional support.

NARRATION OF CASE.

History.—Miss D., the daughter of perfectly healthy parents, was born July 7, 1882. After the first few weeks she was bottle fed, but was well and perfectly nourished until the beginning of this disease. She had none of the infectious diseases and no interruption in her perfect condition until July 4, 1883, when she was a year old. While at some open-air celebration not far from home, she was taken violently ill with chills and fever, and in a few hours a swelling appeared on the right side of the face and about the ear, which some days later broke and discharged through the meatus. With some relief and frequent exacerbations and numerous perforations of the skin in front of and behind the ear, this suppuration continued for five years. The glenoid fossa was completely obliterated and the temporo-mandibular joint ankylosed. Metastatic abscesses appeared at the same time in various parts of the body, notably in the right humerus, the right leg and foot, and the left thigh. The right hip took on the symptoms of hip-joint disease, but after the discharge of pus a complete recovery followed. From some of these openings bones were discharged. There was never any pneumonia.

When she was 6 years old she was operated on in Chicago by Dr. Edmund Andrews. The mastoid was scraped away superficially, and the suppurating middle ear cleared out. Evidently the ossicles were removed. The wound healed, the external auditory meatus became completely obliterated. From time to time during the subsequent nine years abscesses appeared about the mastoid, which were usually lanced and closed up after the discharge of small pieces of bone. These attacks usually appeared in the fall.

She was greatly troubled by the immobility of the lower jaw, and when 14 years old she was anesthetized by Dr. D. W. Graham, who evidently succeeded in producing a fracture of the ramus. This healed, however, in good apposition in a few weeks.

When she was 15 years old she had a severe inflammation over the mastoid, which was followed by an inflammation an inch and a half above the junction of the sagittal and lambdoid sutures. After a time this was opened and discharged several

* Read before the Chicago Neurological Society, 1905.

ounces of pus and some pieces of bone. From this year on she had no more infections anywhere, either over the mastoid or in the extremities, until she was 19 years old. An abscess then appeared near the vertex, discharged large quantities of pus for twenty weeks, and closed spontaneously. A year later another abscess appeared at the same place, which reached enormous size. She came to Chicago and consulted Dr. N. S. Davis, Jr., who put her in Wesley Hospital and opened the abscess.

Examination.—Three weeks later, Nov. 16, 1903, she first consulted me. She gave a clear and unloaded history. During all her life she had had no mental disturbances, was always even tempered, and never suffered from headache, though she frequently had pain in the affected portions of the skull. I found a suppurating sinus near the vertex, and elicited tenderness over the upper portion of the mastoid and the squamous portion of the temporal bone. The jaw was completely fixed by the obliteration of the right glenoid cavity, and the teeth were so close together that they would not admit a knife. The only entrance to the mouth was between the right molars. The right buccinator had been greatly hypertrophied in forcing the food from this buccal cavity between the teeth into the mouth. The external auditory meatus was closed with skin almost on a level with the internal surface of the auricle. There was a considerable scar on the right temple, where an abscess had

Fig. 1.—Diagram of the canalization of the sinuses showing direction and extent of the operation.

been opened and bone discharged. The neck was not stiff, and few enlarged lymph glands were found under the affected ear. Examination of the chest, the abdomen and the blood and urine gave no evidence of disease. There was no history of a typical sinus thrombosis or of any attack of pneumonia, bronchitis or nephritis.

The patient was perfectly active mentally and physically. She had a good appetite and was in excellent spirit. There was no dilatation of either pupil and no evidence of paralysis of the face, the arms or any group of muscles. The pulse was not slowed, and the respirations were full and active, and headache was entirely denied.

First Operation.—From the clinical history and the physical examination, I concluded that the mastoiditis of five or six years ago had produced a sinus thrombosis, with obliteration of the sigmoid, the lateral and a part of the superior longitudinal sinuses, and the discharge of the infection above the lambda. I believed that the proper treatment would consist in an obliteration of the sigmoid, the lateral and the superior longitudinal sinuses by canalization (Figs. 1 and 2) and by the complete eradication of all suppuration in the antrum, if left behind, and in the attic and the air cells in the root of the zygoma. Accordingly, with chloroform anesthesia, an opera-

tion was undertaken as if to approach the antrum. This was found undisturbed and full of pus and connected by a defect in the tegmen with an abscess of great size in the middle fossa. This abscess was opened an inch behind and an inch above the middle of the external auditory meatus, and discharged such an enormous quantity of pus that further operating was discontinued in alarm. The abscess was extradural; the pus was of a dark-gray color, and not less than four ounces drained out during the operation and before the dressings were applied. It seemed impossible that such an enormous quantity of pus could be harbored in a skull with a perfectly functioning brain. The patient came out of the anesthesia without any trouble and did perfectly well.

Second Operation.—After two weeks a second attempt was made to eradicate the suppuration. The mastoidectomy was completed and the external auditory meatus opened to the bottom of the antrum. No evidence of the facial nerve was discovered at this time. There was scanty and much cicatrized skin in the neighborhood of the mastoid with which to close in the defect. The scalp was opened from the mastoid to the suppurating focus on the top of the head, and a channel of bone about 1 cm. wide at the bottom and something more than this at the top was chiseled out through both tables of the skull, laying bare the bottom of the sigmoid sinus, the lateral sinus and a portion of the superior longitudinal sinus. These channels were found covered with exuberant granulations. Nearly all of the pus had drained away during the two weeks' intermission. The patient endured the anesthesia splendidly. This operation was performed on December 4, and during the following three weeks she did well, the suppuration diminished, and the bone became rapidly covered with skin or granulations, but soon after Christmas the temperature suddenly rose, and an erysipelas spread from the neighborhood of the mastoid

Fig. 2.—Diagram showing the method of canalizing the superior longitudinal sinus. One flap of scalp is turned in over the skull. The other will be held down in the same manner by the gauze.

over the face and scalp. This lasted several days and disappeared.

Third Operation.—On Jan. 22, 1904, a third operation was performed to remove the granulations from the bottom of the wound, which extended from the lambda to the mastoid, and to close a large defect over the mastoid which had resulted from the inadequate supply of scalp. The defect was divided with a peninsula of skin. No osteal evidence was necessary. Following this operation the epidermization of the wound was rapid, and the patient left the hospital on March 1 without any large dressing. The only ulcer was over the mastoid. During the succeeding year and a half there were a number of slight attacks of pain with inflammation in the external auditory meatus, which subsided after a few days by the discharge of a little pus.

Fourth Operation.—She consulted me on Oct. 28, 1905, on account of such a suppuration, which appeared to be in the root of the zygoma, but very superficial and trifling. She also spoke of the possibility of restoring the function of the articulation between the mandible and the temporal bone. I found the jaw fixed, as it had been since she was a year old, but believed that the articulation on the opposite side of the jaw was perfect, and that the internal ligaments of the jaw between the lingula and the spinosa were intact. It seemed possible to separate the ear from above downward from the bony meatus without danger of anemic necrosis (Fig. 3) and thus approach the obliterated glenoid fossa by retracting the parotid forward and baring the lateral surface of the obliterated articulation. Thus it would be possible to eradicate the infection at the root of the zygoma and remove enough bone about the condyle of

the mandible to restore the joint. I had the assistance and advice of Dr. Charles P. Pruyn in this matter, who was extremely guarded in his prognosis, fearing the incompetency of the joint ligaments. This operation was undertaken Nov. 3, 1905, with gas and ether anesthesia. Without ligating any large blood vessel, the lateral aspect of the temporo-mandibular articulation was laid bare, the parotid and its contained branches of the facial nerve were retracted ventralward and downward, and the auricle, which was separated from the bony meatus, was retracted downward and backward. The outline of the joint was made out and found to be rather broader than normal on account of the adventitious growth of bone. An artificially curved condyle was then marked out with the chisel and the necessary bone in the zygoma and the glenoid fossa chiseled away. It required nearly 2 mm. of channel for the use of the chisels, and no cartilage was discovered in the course of the excavation. No accident occurred. The bone was somewhat eburnated, and showed no trace of infection except in the root of the zygoma, where it was expected. The mouth was not opened into from the operation wound. When the ankylosis had been entirely chiseled away, the jaw was movable, showing no ankylosis on the opposite side. The anesthetist was able to introduce the width of two fingers between the incisors. This was considered adequate. In order to

duce her thumb without force to the metacarpal joint. Forceful extension of the jaw produces as much pain on the left as on the right side.

SUMMARY.

To summarize the accomplishments of the treatment I have instituted, I would call attention to the presumptive diagnosis of a sigmoid sinus, a lateral sinus and a superior longitudinal sinus thrombosis. So unusual a condition could not be premised as an accompanying extradural abscess of enormous size, probably containing not less than six or eight ounces of pus. The lack of pain and symptoms of sepsis would ordinarily deny the diagnosis.

The complete evidences of the antrum and its connecting air cells was the prerequisite to any effective treatment, and the alarming discharge of pus through the antrum and afterward through the opening in the squamosa constrained me to await the shrinking of the abscess cavity and the diminution of the field of operation to the sinuses alone.

At the second operation the external auditory meatus was restored in the hope of bringing the middle ear to some use. A communication was made between the bottom of the antrum and the internal wall of the tympanum. The sigmoid was opened immediately behind the mastoid, and the channel which the probe discovered leading toward the occiput was completely canalized. A few bits of infected bone were removed mechanically, which would have required months or years to be carried away in the discharges.

The temporo-mandibular joint has, I believe, been permanently restored and the function of the jaws for the first time made possible. The teeth can be treated now and kept for some time for mastication and for cosmetic purposes.

The patient has been relieved of the dangers of a chronic pyrogenic function.

HYPEREMESIS GRAVIDARUM.*

CHARLES ROSEWATER, M.D.

Professor of Obstetrics, Creighton Medical College.

OMAHA, NEB.

Fig. 3.—Diagram showing the blood supply (a, b) of the auricle after a complete mastoidectomy. The artificial articulation between the zygoma (z) and the mandible (G) under the retracted parotid is shown. A strip of fascia (F) and muscle taken down was turned into the new-made joint.

establish a permanent separation between the mandible and the temporal bone, the incision was extended upward somewhat, and a piece of fascia belonging to the temporal muscle was cut away, making a flap about 1 cm. wide and 4 cm. long. It contained an abundant blood supply in the bits of muscle attached to it. This flap was carefully drawn into the artificial articulation and held in place by the natural apposition of the bones. The wound was now closed, with a liberal drain in the immediate neighborhood of the artificial joint and dorsalward of the parotid.

Postoperative History.—Since the operation the patient has done well; there has been a discharge of parotid secretion and some pus from the wound, but there has been no disturbance of temperature. On first waking from the anesthesia, the patient discovered that she could, for the first time, protrude her tongue far enough to see it, and she exercised this newly acquired maneuver until the tongue was sore. The articulation has not been painful at any time, and voluntary movements are satisfactory. The teeth are so defective and sore that chewing is somewhat painful, but she greatly enjoys it. The jaw can now be voluntarily opened so that she can intro-

duce her thumb without force to the metacarpal joint. Forceful extension of the jaw produces as much pain on the left as on the right side.

By this term is usually meant that aggravated uncontrollable form of vomiting of pregnancy which resists local as well as constitutional treatment, and which so reduces the patient's vitality that it very seriously endangers her life. Occasionally, deaths directly due to this cause have been reported, so that a very serious and difficult problem confronts the physician who has charge of such a case. A large number of these patients abort as the result of the irritation of the uterus caused by the violent fits of retching and vomiting; this relieves by removing the source of the irritation.

The lives of a number of these patients may be maintained for a time by rectal alimentation, but, unfortunately, by many this mode of feeding is not borne very well, especially if it must be kept up for a long time. Realizing, however, that the vomiting of pregnancy usually abates toward the end of the third or the beginning of the fourth month, the physician's aim should be to sustain the patient until this time shall have been reached. This can be done in some cases, but will fail in others. The patient may waste away and lose strength, retaining no food at any time of the day or night, either by mouth or rectum, despite the faithful

* Read before the Omaha-Douglas County Medical Association, 1905.

use of such remedies as cocaine, oxalate of cerium, carbolic acid, essence of pepsin, lime-juice and pepsin and a host of others, which occasionally give relief in the milder form of vomiting.

In some cases in which malpositions of the uterus have been found and rectified, the condition has been ameliorated so that the patient's life could be sustained until the time when things naturally mend, or until such a period as would render possible the induction of premature birth with some chance of survival of the child.

In some instances local application to the cervix of carbolic acid or nitrate of silver or local electrolysis to the cervical canal with a mild current have succeeded in ameliorating the condition and rendering it tolerable.

Where these have failed, some have advised and even carried out instrumental dilation of the os. This is a *remedium anceps*, in that it is liable to be attended by partial separation of the ovum and to be followed by abortion. Particularly is this the case when the dilator is inserted too high and the membranes are ruptured. The emptying of the uterus usually relieves the vomiting, but by so doing in the first six months the life of the fetus is sacrificed, a procedure not justifiable except when, as a last resort, it is carried out to save the mother's life after all other methods of treatment have failed.

The vomiting of pregnancy being a reflex symptom of the uterine disturbances incident to pregnancy, its degree of intensity depends on the severity of the local pathologic conditions, together with the sensitiveness of the nervous system.

It is more severe, therefore, in patients with extremely nervous temperament, and particularly so in those with pronounced pathologic conditions about the uterus. Endometritis, malpositions and lacerations are the local conditions most frequently aggravating the ordinary mild vomiting of pregnancy, and their appropriate treatment will usually relieve the vomiting, if not entirely, at least sufficiently to make the condition tolerable. It is not my intention to dwell minutely on the various therapeutic measures applicable in these cases. I simply desire to call attention to these conditions that in any given case they may be looked for, and, if found, corrected.

It is to be presumed that the physician in examining such a patient will eliminate all other possible sources of uncontrollable vomiting, such as incarcerated hernia, intussusception, pyloric stenosis, cancer or ulcer of the stomach, kidney disease, brain disease or appendicitis, arriving by exclusion at the proper diagnosis corroborated by the results of local examination.

Many physicians treat this vomiting in a routine manner without paying due regard to the conditions underlying or aggravating it.

When no local disease or malposition is found, in other words, in a simple case of vomiting of pregnancy, I usually advise my patient to stay in bed at least an hour after breakfast, and prescribe ingluvin, 10 grains before and after each meal. The recumbent posture, with restriction of the morning meal, and some pepsin compound is all that is necessary to control the milder forms of vomiting of pregnancy. In the more severe forms usually, but not always, some pathologic condition, such as already indicated, will be found, which, if rectified, will lead to satisfactory results. At the Nashville session of the American Medical Association a physician from Ohio related the details of a case in which, after everything he and others could think of had been tried

without success, it was decided to empty the uterus in order to save the patient's life. Electricity was used, and the applications were made at regular intervals, either daily or on alternate days. The author reported the effects of each application in about the following language: "After the first two applications there was no perceptible effect. After the third application there was some amelioration of the symptoms. After the fourth application the vomiting ceased. After the fifth application pains began and after the sixth application the fetus was expelled."

I criticized him for having made the fifth and sixth applications of electricity, thereby causing the expulsion of the fetus, when the fourth application, by relieving the vomiting removed the excuse for the abortion.

In this connection I wish to report a case which occurred in my practice three years ago, and which aptly illustrates the point I made in the above criticism.

Patient.—Mrs. —, aged 39, mother of three children, called me in February, 1902, on account of persistent and violent vomiting. She had missed her last menstrual period and thought herself about six weeks pregnant.

Examination.—This proved her suspicions to be correct, and showed a lacerated, displaced cervix, with normal position of uterus. The bowels and kidneys were normal, as was also every other possible source of trouble.

Treatment.—Ingluvin was given before and after meals, absolute rest in bed was insisted on, and a diet of milk and broths was ordered. This being of no avail, phenolated essence of pepsin with bismuth and hydrocyanic acid were given, with like result. The cervical canal was treated with carbolic acid and iodine, and a glycerin tampon applied. Feeding by the mouth was stopped and rectal alimentation resorted to. The vomiting still continued without abatement and with evidences of increasing debility. At this stage I was unavoidably detained at home by sickness for a week, during which time she was in the care of two other reputable physicians, one of whom tried to relieve her by dilating the os. Her condition did not improve, the vomiting continued and when I returned I found her extremely emaciated, losing flesh and strength rapidly, vomiting blood and mucus and with her teeth loose, gums raw, sore and bleeding, her mouth emitting a fetid odor. Inquiry elicited the fact that neither of the physicians had given any mercurial preparation, so that this condition of the mouth must be interpreted as an aggravated form of the salivation so often attending the earlier months of pregnancy, just as the vomiting was an aggravated form of the emesis ordinarily occurring in this condition.

Things had come to a pass where something radical had to be done to save the patient's life, so with her and her husband's consent, reluctantly given, I proceeded under anesthesia and with strict asepsis to dilate the os thoroughly; I introduced a bougie into the uterus up to the fundus and left it there. The vagina was packed with iodoform gauze and the patient left quietly in bed. Within two hours pains began and continued for about thirty-six hours; as no hemorrhage occurred and the temperature remained normal, I left the bougie in the uterus for forty-eight hours. During this time the vomiting had ceased and when I removed the vaginal tampon I found nothing had been expelled from the uterus. I now carefully removed the bougie and again reassured myself by careful examination of the presence of pregnancy. The vomiting having ceased, I told my patient that I would desist from all further attempts to empty the uterus and would now try to save the child as well as the mother. I gave a uterine sedative, kept the woman in bed for ten days, and began a process of feeding. She retained the food, the vomiting did not recur, and as soon as the gums were restored to a good condition by appropriate local treatment she began taking solid food. The further course of the case was uneventful and on Oct. 4, 1902, I had the pleasure and satisfaction of delivering the patient in an easy labor of a healthy, living child, which to-day, three years later, is hale and hearty.

What I want to emphasize is the fact illustrated by the

two cases cited above, that when in pregnancy, for just and lawful reasons, the emptying of the uterus is resorted to, and during the operation improvement in the fundamental conditions supplying the excuse for the abortion occurs, it is the duty of the physician, if not too late, to cease in his attempt to cause abortion, and to make all efforts to save the child as well as the mother.

This could probably have been done in the first case cited, but evidently it was not thought of.

THE OPERATIVE TREATMENT OF FRACTURES.

JAMES A. KELLY, M.D.
PHILADELPHIA.

In no class of surgical cases is there demanded the mechanical skill, the anatomic knowledge and the perseverance that is required in the treatment of fractures. It has, at all times, received close attention and careful study; yet it is perfectly evident, from the great number of cases which so frequently tax our ability to the utmost, and are followed not only by unsightly deformities, but by poor functional results, that a decided change from the heretofore conservative methods of treatment is necessary in many cases if perfect approximation of the fractured ends of the bone and good functional results are desired.

Since the introduction of the x-ray as a means of diagnosis, the difficulty of complete reduction and perfect approximation of the fragments is shown, and masses of bone, which were formerly termed "exuberant callus," prove to be due to the displacement of the fractured ends and comminution of the fragments at the seat of fracture.

In a great number of cases the desired result—complete reduction and perfect approximation—can be obtained by only one means, the direct replacement and fixation by operative methods. The treatment of fractures by open operation is one of the many advances that has been made in recent years. It is only within the past decade that surgeons have realized that dissolution in continuity of bone can be treated in the same manner as dissolution in continuity of other structures; that is, by direct restoration and perfect coaptation of the parts; and that operations on the osseous system can be performed with as great a degree of safety as in operations involving the soft parts. Many authorities are inclined to object to the advisability of operating on closed fractures. They consider that in all cases good functional results can be obtained by position and fixation in splints after proper reduction, and that the converting of a closed fracture into an open one is not only unnecessary, but in most cases dangerous, on account of the risk of sepsis taking place. There is a growing tendency, however, among surgeons of the present day to operate on many cases of closed fractures which can not be perfectly reduced, or which, when reduced, fail to remain so, as shown by the x-ray photograph, and these men have from time to time reported their results.

It is with the laudable object of adding to the literature of the subject that the present paper is presented to the medical profession. While the operative treatment of closed fractures was the primary incentive for writing this paper, the operative treatment of open fractures, ununited fractures, etc., will be considered.

Through the courtesy of Drs. Rolles, Cushing, Monks,

and Lund of the Boston City Hospital, and Dr. H. C. Deaver of St. Mary's Hospital, Philadelphia, I have been afforded the permission to report the series of cases on which this article is based. I observed the cases while house surgeon at the two above-mentioned institutions. The series consists of 23 cases, the nature of the fractures being as follows: Closed fractures, 8 cases; open fractures, 12 cases; ununited fractures, 2 cases; and deformity following fractures, 2 cases.

In the operative treatment of fractures the subject may be classified as follows:

- I. The Operative Treatment of Closed Fractures.
- II. The Operative Treatment of Open Fractures.
- III. The Operative Treatment of Ununited Fractures.
- IV. The Operative Treatment of Separated Epiphysis and Fractures Associated with Dislocations.
- V. The Operative Treatment of Deformities Following Fractures.

I. THE OPERATIVE TREATMENT OF CLOSED FRACTURES.

Until recent years the only method of treatment of closed fractures was the employment of external dressings, as splints, plaster-of-paris casts and bandages, etc., with and without traction, with the object in view of approximating the fractured ends of the bone, correcting displacements and holding in place fragments which tend to unite with deformity. While in general, many cases recovered with good anatomic and perfect functional results, in other cases the subsequent deformity, the failure to obtain union and the frequent loss of function show only too well that perfect results can not be obtained at all times by conservative measures. The constant use of the x-ray and examination under anesthesia show that in many cases proper reduction can not be obtained and the fractured ends held in perfect approximation by the ordinary methods of external fixation.

The perfection of surgical technic and wound asepsis has produced extremely rapid progress in all branches of surgery since the introduction of Lister's method of antiseptics. Their results are strikingly seen in the great reduction of mortality following the antiseptic methods in the treatment of compound fractures and the comparatively little risk in all operations on bones, as osteotomy, resection, etc. Since it is now possible to operate almost always without wound infection, closed fractures may be operated on with as little risk as operations on other parts of the body.

Scudder's statistics on the results obtained in the non-operative treatment of fractures are interesting. They are based on the observation of cases, three to five years after injury, treated at the Massachusetts General Hospital. In fractures of the hip, the results were poor in 81 per cent. In fractures of the thigh, perfect functional results were obtained in children; in adults, 31 per cent. were perfect, and 69 per cent. imperfect, and in old age none was perfect. In fractures of the leg, poor results were obtained in 60 per cent. of closed fractures, and poor results in 79 per cent. of compound fractures. Since the introduction of aseptic methods of treatment of compound fractures, the mortality has fallen from 68 per cent. to 2 or 3 per cent. at the present time.

Senn states that "the adoption of rigid antiseptic precautions in the treatment of compound fractures has reduced the mortality from 50 to 70 per cent. almost to nil, and the same has rendered operations for ununited fractures nearly devoid of danger."

The financial depreciation of the patient is to be considered in the treatment of fractures, especially those of the lower extremity. Mr. Lane considers that the financial depreciation of the laborer as a mechanic amounted in fractures of the tibia and fibula to nearly as much as 70 per cent. of his original value, when treated by non-operative methods. This he ascribed as being due to alterations in the line of pressure through the several joints of the lower extremity, resulting from the somewhat complicated deflection of the lower fragments from their original relationship to the upper. Mr. Lane argues that to pursue the present mode of treatment was highly improper, since by operative measures, entailing a minimum of risk to the patient, the fragments could be brought into apposition and so retained with perfect accuracy, with the result that the skeletal mechanics of the individual remain as perfect after the injury as before.

While it is true that there are many surgeons who entirely condemn the operative treatment of closed fractures, it is an undeniable fact that there are many surgeons, and their numbers are increasing, who consider this method justifiable in all complicated fractures, and in many fractures in which perfect reduction and approximation can not be obtained. Golding-Bird states that "the merit of the operative interference in closed fractures does not stand on any different footing from that of other surgical procedures; its value should be assessed, not by one fact only, but by all those results of its employment taken together, which tend for the good of the patient and the complete reduction of the fracture, which must and can alone determine the right course to adopt."

The results desired in the treatment of all fractures are: (1) The perfect reduction, approximation and retention of the fractured ends of the bone; (2) the prevention of subsequent deformity; (3) the retention of perfect alignment of the fragments; (4) the prevention of "exuberant callus"; and (5) the prevention of non-union and pseudarthrosis.

Many conditions prevent the accurate adjustment of the fragments in fractures of the long bones. These not only prevent reduction, but are often the cause of deformity, delayed union, non-union, neuritis, paralysis, muscular atrophy, loss of function and impairment of the general health. The most frequent obstacles to the complete reduction of the fractured ends and their permanent retention are: (1) The interposition of soft parts, as muscles, nerves, blood vessels and fascia; (2) the retraction of normally stretched tissues which after fracture have no resistance offered to them; (3) the piercing of adjacent muscles and fascia by the sharp ends of the broken bones; (4) the displacement and interposition of comminuted fragments; and (5) hemorrhage into and inflammation of the soft parts. This last condition has always been greatly underestimated. Mr. Lane states that "the bruised and lacerated soft parts are infiltrated, often very extensively, with blood, and are in a condition of very considerable inflammation and tension. The fragments of bone can not be placed or retained in accurate apposition by any process of manipulation or of extension, or of fixation in splints, castings, etc. We have had enough experience now to know that, providing the fragments have become displaced from one another, whether the fracture be spiral, transverse or oblique in direction, the amount of displacement, overlapping or alteration of the axes of fragments on one another varies with the hemorrhage

into and swelling of the lacerated soft parts which surround the bone or bones. We also know that if these soft parts are allowed to remain in their shortened condition for any length of time, the amount of force required to restore them to their original length is necessarily very great, and varies directly with the length of the interval following the fracture.

CLOSED FRACTURES MOST SUITABLE FOR OPERATIVE INTERFERENCE.

While it is not advisable or necessary to operate on all closed fractures, yet there are certain bones which, when fractured, generally demand operative interference if we would obtain the best anatomic and functional results. Many authorities still maintain that no closed fracture should be converted into an open one, but there are some fractures in which even the most conservative surgeons will admit that were it not for the danger of sepsis intervening, better functional results could be obtained by operation. Among such may be mentioned the following: (1) Fractures of the neck of the femur in patients under 50 years; (2) supracondyloid fractures of the femur; (3) fractures of the patella; (4) spiral and oblique fractures of the tibia, either alone or in combination with fractures of the fibula; (5) fractures of the clavicle, with marked displacement; (6) fractures of the upper end and of the condyles of the humerus; (7) fractures of the olecranon, with marked separation of the fragments; (8) fractures of the middle of the radius; (9) fractures of the spine and skull. In all cases in which marked comminution of the fragments is present and when reduction is impossible, in oblique and spiral fractures of the bones of the extremities, operative intervention is justified. Many of the deformities, pseudarthrosis and loss of function seen to follow fractures, will thus, in most cases, be obviated. The unsightly deformities which so seriously destroy the usefulness of the part and predispose to refracture will be prevented. Fractures complicated by severe injury to adjacent structures urgently demand operation. Under this heading may be included fractures, in which pressure is brought to bear on neighboring viscera, nerves and blood vessels, fractures associated with dislocations, and fractures involving joints.

Not only does non-union often result from misplaced fragments, but excessive callus formation is bound to occur. Nerves and blood vessels are liable to be involved in this excessive attempt of nature to repair the loss of bony continuity, and involvement of such structures is seen in the frequent neuritis and edema of the parts following malunion. When this excessive callus is formed at the seat of fractures involving joints, impairment and at times total loss of function is the result. Excessive callus is formed only when perfect approximation of the fragments is not obtained.

ADVANTAGES AND DISADVANTAGES OF THE OPERATIVE TREATMENT OF CLOSED FRACTURES.

Compared with the dangers of sepsis, which is the chief argument against operation, the advantages to be obtained by the surgical intervention in closed fractures, are manifold. They may be enumerated as follows: (1) The patient is at once relieved from any pain which might be caused by the movement of one fragment on another; and of the discomfort due to tension, caused by the extravasated blood. (2) Accurate approximation and retention of the fractured ends is possible by means of instruments and appropriate methods of internal and external fixation. (3) Shortening and de-

formity are prevented. (4) Clots of blood and detached fragments of bone may be removed and neighboring structures repaired. (5) Excessive callus formation is prevented by accurate approximation, and in fractures involving joints subsequent limitation of motion and deformity are prevented. (6) Pressure on neighboring structures is removed. (7) Associated dislocations may be properly reduced. (8) The period of disability is considerably lessened, as union is practically by first intention, and consequently very rapid and perfect. (9) The skeletal mechanics of the patient are left in the condition in which they were before the injury.

The disadvantages of the operative treatment of closed fractures are: (1) The liability of infection; (2) the danger of necrosis of the fractured ends; (3) the presence of a skin scar.

These disadvantages, however, are outweighed by the advantages, and in all cases in which complete reduction, perfect approximation and retention can not be obtained by conservative means, when complications exist, and when the preservation of the skeletal mechanics, especially in laborers, is an important factor, there should be no hesitancy in converting a closed fracture into an open one, for the patient's good.

TIME OF THE OPERATION.

In certain varieties of fractures in which it is known from experience that perfect reduction and retention can not be obtained by conservative means, as in spiral and oblique fractures of the middle and lower third of the tibia, it is advisable, after the preliminary x-ray photograph has been taken, to operate immediately after the injury, providing the patient has suffered no shock at the time of the accident. By so doing, reduction will more easily be accomplished, the edema of the soft parts will be avoided, the formation of fibrinous tissue between the fractured ends and contraction of the soft parts will be prevented, approximation of the fractured ends can be accomplished without the necessity of resection and consequent shortening, and healing by first intention will be the rule. Some authorities prefer to wait for a week or ten days before operating, until the effused blood has been absorbed. By so doing, they claim that the risk of infection is reduced to a minimum.

TECHNIC OF THE OPERATION.

There are many methods of internal fixation of the fractured ends of the bone in use by various surgeons. The technic of exposing the fragments is practically the same in all cases, minor changes being required to suit the individual case. In some cases internal suture of the fragments is unnecessary, while in other cases permanent complete reduction and perfect approximation can not be obtained without some method of internal fixation. Two classes of cases will therefore be described:

1. *Repair Without Internal Fixation.*—In this class are included: (a) Fractures in which reduction is prevented by the interposition of soft parts between the fractured ends of the bone. (b) Fractures in which there is irregularity of the fractured ends, so that, when the fragments are brought into apposition they become locked. (c) Fractures in which apposition can readily be maintained by external splinting after reduction has been accomplished. The best example of this class is a dentated supracondyloid fracture of the femur. (Case I.)

The skin for a considerable distance above and below the seat of the fracture should be carefully cleaned

with soap and water and the hair removed. The part is again cleaned with tincture of green soap and sterile water, and then with 70 per cent. alcohol. Exsanguination by means of a tourniquet or an Esmarch bandage is not advisable. While its advantages are considerable during the operation by giving a bloodless field, subsequent bleeding from large and moderate-sized vessels is not recognized, and is liable to promote wound infection, not only on account of the blood clot which forms, but by the inevitable formation of a small sinus along which infection may travel from the surface. All bleeding should be controlled as it arises. The incision through the skin and superficial fascia should be sufficiently large to permit of thorough inspection and to allow of protrusion of the fractured ends through the wound, if necessary. The muscles should be separated in their intermuscular planes, when possible, and if not, in a direction parallel to the course of their fibers. Nerves and blood vessels should be carefully avoided. On reaching the periosteum, it will be found to be separated to a variable extent, and at times torn completely across. If the periosteum is not torn, it should be divided longitudinally, and the seat of the fracture exposed by retracting its edges. All bleeding should be controlled, and any blood clot present should be removed by means of dry sponges. Intervening structures should be carefully disengaged from the rough edges of the fragments and placed in their normal relations, suturing torn structures with fine catgut, if necessary. Detached fragments of bone should be removed. If the operation is performed shortly after the injury, it will be found possible by extension and manipulation to bring the fractured ends into approximation and lock them together without resecting the fractured ends. If this is possible, an assistant should hold the part in its normal position from this stage until the operation is completed and the external splints have been applied. Irrigation of any kind is not advisable, as all irrigating solutions tend to lower the vitality of the tissues. Blood clots can best be removed by dry gauze sponges. The edges of the periosteum, the muscular layers and subcutaneous tissues should be united by interrupted or continuous layers of fine catgut, and the skin by interrupted or subcuticular horsehair or silkworm gut. The wound should then be sealed with a collodion dressing and a dry protective dressing of gauze applied external to this. Immobilization should be made by appropriate splints, or by a plaster-of-paris dressing, care being taken as to the position of the parts, and also that the joints above and below the seat of fracture are put at rest.

2. *Repair with Internal Fixation.*—While in a small number of cases perfect approximation may be obtained without the use of internal methods of fixation, the majority of cases requires it. This is especially so in spiral fractures of the tibia, in fractures of the clavicle, humerus, radius, patella and olecranon. The technic of operations on the patella is so perfect and the procedure is so well established, that it will not be described. The part is prepared aseptically and the fractured ends of the bone exposed, as in the methods above described. If it is found necessary to resect the ends of the fragments, in order to bring them into apposition, this can best be performed by protruding the ends through the wound, and then resecting as desired. This is feasible, however, only when one bone occupies the part involved, as in a fracture of the humerus or femur. In other cases the resection must be performed *in situ*. If the operation is

performed shortly after the time of the injury, resection is rarely, if ever, necessary. It is only in those cases in which, for some reason or other, the operation is not performed for several weeks after the time of the injury, fibrous tissue has formed about the ends, retraction of the tissues and shortening of the limb has occurred, that resection is required.

While some surgeons prefer to make the resection *in situ* by means of a Jeffray's chain saw, a Gigli saw, a Wyeth's saw, or a Hey's saw, the author considers that less damage is done to the soft structures, and particularly to the periosteum, by a chisel. This is preferred, because there is no danger of wounding the periosteum, separation of the periosteum from the bone is not required to such an extent as when a saw is used, the line of resection can be made at any angle, and the ultimate shortening is much less. The line of fracture, in most cases requiring operation, is oblique or spiral in direction, and as resection can be performed with saws only in a more or less transverse direction, the loss of bone by this method is unnecessarily great. Resection should be so performed as to leave the limb in its normal position, as to its rotation and its axis. When fibrous tissue has formed between the fragments, it should be removed by means of a curette or a gouge and the ends of the bone freshened by removing a small portion with a chisel. While a transverse section is the best for suturing and permanent approximation, it is in most cases performed at a too great sacrifice of the length of the bone, and should be used only when necessary. Small defects lost by comminution of the fragments will be repaired by the periosteum. The chief aim in operating should be to bring together, by direct fixation and complete immobilization, the different anatomic structures, permanently into their normal relations, which is always the ideal process of repair.

METHODS OF INTERNAL FIXATION.

When perfect reduction and approximation have been accomplished, internal fixation may be performed by one of various methods, depending on the selection of the surgeon. It may be stated here that the following methods of internal fixation are applicable, not only in recent closed fractures, but also in open fractures, in cases of non-union, mal-union and pseudarthrosis.

The mechanical appliances for securing internal fixation may be divided into the following classes:

1. Fixation by means of absorbable sutures. In this class are included sutures of plain catgut, chromicized catgut, kumol catgut, iodinated catgut and kangaroo tendon. Of these the only ones which will hold the fragments in place until union takes place are heavy (No. 4) chromicized catgut and kangaroo tendon.
2. Fixation by means of non-absorbable sutures. These consist of silk, silkworm gut, Pagenstecher's thread and iron and silver wire. When any of these sutures are used, they are generally retained permanently and become ensheathed.
3. Fixation by means of bone and metallic ferrules, ivory, bone and metallic plugs to be placed in the medullary cavity; and ivory, bone and metallic nails.
4. Fixation by means of absorbable or non-absorbable sutures combined with ligating by means of silver or iron wire passed circumferentially around the fragments.
5. Fixation by means of instruments which consist of specially designed plates and screws, and are used in different methods of resection. In this class are included the instruments of Kestley, the metallic double

staple of Gussenbauer, the plates and screws of Agnew and those of Steinbach.

6. Fixation by means of Parkhill's clamps. This method consists in fixing the fragments by means of two screws driven into the ends of each fragment and held immovable by means of external plates.

Of the various methods given above, there is no one which can be used without some external retentive apparatus, as splints or plaster-of-paris dressings. While all the methods have their advantages, the writer considers that the use of an absorbable suture, preferably, heavy (No. 4) chromicized catgut, meets all the requirements of an ideal suture for retaining the approximated ends in position, and has a greater range of applicability than any of the other methods in use. Non-absorbable sutures very frequently prove an irritant to the tissues, lower their vitality, increase the chance of infection, and, very frequently, require subsequent removal. The same may be said of bone and metallic ferrules, intramedullary plugs and metallic nails and screws. A great danger in the use of silver wire is the tendency for the wire to break, either at the point of twisting, or more frequently, it is cut by the sharp edge of the bone hole by slight strains, which so often occur before the external splint or plaster-of-paris dressing has been applied. The objections to the buried plates of Steinbach and of Agnew, and the method of Kestley, are that the screws very frequently pull out; these methods require a second operation for the removal of the plates, and the methods of resection used necessitate too great sacrifice in the length of the bone. These methods and that of Parkhill do not prevent considerable lateral mobility, and the presence of external openings, along the site of the screws in the latter method, is a constant source of danger in the production of infection.

As all methods require some form of external retentive apparatus, it would seem that the ideal form of internal fixation is the heavy (No. 4) chromicized catgut. This is condemned by some authorities on account of the stretching of the sutures, which may occur while applying the external dressing. This danger, however, is very small, while, on the other hand, it is an absorbable suture where the risk of infection is small, the direct approximation is perfect by this means, a secondary operation is not required, and the parts are left in an anatomically perfect condition.

In Cases 1, 9, 18, 19, 20 and 23 no bone suture was used. In Cases 2, 3, 4, 5, 6, 7, 8, 10, 11, 21 and 22 chromicized catgut (No. 4) was used to hold the fragments in apposition. In Cases Nos. 15, 16 and 17 silver wire was the suture used.

TECHNIC OF SUTURING WITH CATGUT.

Having arrived at the stage where the fractured ends are in perfect apposition, the suture holes should be drilled with a Lentz, Brainard, Hamilton or Gaillard bone drill. The suture holes should be placed one-fourth to one-half inch from the fractured edge and at intervals of every half inch. When the resection is performed *in situ* the suture holes should be made only through the compact bone into the medullary cavity, and not through the entire diameter of the bone. If the ends have been brought through the wound for resection, the holes may be made through the entire diameter of the bone. The catgut sutures may be introduced through the suture holes by means of a silkworm gut carrier, which is first passed on a curved needle reversed. After all the sutures have been introduced and the fractured ends approximated, an assistant should be assigned the

task of holding the extremity carefully until the final external dressing has been applied. The sutures are now tied securely and the excess cut away. The periosteum is united by interrupted catgut sutures. The overlying soft parts are united as described above and the wound closed without drainage. A collodion dressing is then applied, and immobilization secured by a plaster-of-paris dressing, so applied as to prevent angularity or rotation at the seat of the fracture and fixing the joint above and below the seat of fracture.

Immediate suture of the fragments is not necessary in all varieties of fractures. In some fractures about joints the fragments are so small, as in a fracture of a condyle of the humerus or of a malleolus in a Pott's fracture, that they may be held in perfect apposition by suture of the periosteum. For this purpose medium-sized (No. 1 and No. 2) chromicized catgut may be used and the fragments permanently retained in place by a suitable external splint or plaster-of-paris dressing.

The external dressing should be applied in such a manner as not to require a change throughout the entire treatment. If plaster of paris is used a window may be cut over the seat of fracture, so that the wound may be inspected when necessary, and the skin sutures removed at the proper time.

II. THE OPERATIVE TREATMENT OF OPEN FRACTURES.

The results obtained by conservatism and aseptic surgery are strikingly shown to-day in the treatment of compound fractures. Prior to the introduction of antiseptics and asepsis, amputation of the limb above the seat of a severe compound fracture was the rule. Later, when conservative methods were introduced, excision of joints near the seat of fracture was invariable, while amputation was the measure of last resort. Death from sepsis was very frequent. The results of conservative and aseptic surgery of to-day are shown by the statistics of Scudder, who states that "the mortality has fallen from 68 per cent. a few years ago, preceding the introduction of antiseptics, to 2 to 3 per cent. at the present time." To-day, compound fractures, if properly treated, are attended by a very low mortality, and in most cases a good functional result is obtained.

In the treatment of all compound fractures attempts should be made to disinfect the wound thoroughly, so far as possible, to restore the parts to their anatomic relations, to institute adequate drainage and to immobilize the part until union is effected.

TECHNIC OF THE OPERATION.

The limb above and below the wound should be shaved and thoroughly cleaned with tincture of green soap and sterile water and 70 per cent. alcohol. The wound should then be thoroughly irrigated with normal salt solution. It is advisable in all cases to enlarge the wound and explore the seat of fracture. Torn muscles and nerves should be repaired and all bleeding vessels ligated. If the external wound is small and was evidently made by the fracturing force, rather than by a sharp fragment of bone, the chances of infection are much less. If one of the fractured ends protrude through the wound, the chances of carrying infection are great, and its end should be trimmed off with rongeur forceps until healthy clean bone is reached. Internal fixation should be performed with heavy chromicized catgut, as in the method detailed in the treatment of closed fractures. The remaining technic differs from that in closed fractures only in the fact that drainage should be used in every case.

If the chances of infection are great, internal fixation is preferably made with silver or iron wire, which should subsequently be removed. Drainage is best obtained by means of rubber tissue or a cigarette drain. A sterile gauze dressing should be applied and immobilization secured by a plaster-of-paris splint. A window should be cut through the latter so that frequent observation and dressing of the wound may be made. Drainage may be dispensed with in a few days if infection has not occurred. For the purpose of protecting the plaster-of-paris dressing, in case irrigation of the wound is required, the "window" and the surrounding plaster should be covered with rubber tissue. When wire has been used to secure internal fixation, it may be removed by a subsequent operation after union has become firm.

III. THE OPERATIVE TREATMENT OF UNUNITED FRACTURES.

In the class of ununited fractures may be included all cases of delayed union and pseudarthrosis. The chief causes of non-union are: (1) Failure of approximation of the fractured ends, due to the intervention of muscles, nerves, blood vessels, etc.; (2) muscular action; and (3) faulty immobilization. Constitutional diseases play but a small part in the prevention of union. Examination in such a condition shows the fractured ends to be separated and the intervening space filled by muscles, etc., or fibrous tissue. The ends of the bone are smooth and a condition of pseudarthrosis is frequently present.

TECHNIC OF THE OPERATION.

The technic of the operation consists in rendering the skin aseptic and exposing the seat of the fracture by the method given in the treatment of closed fractures. The periosteum should be divided longitudinally and its edges retracted. All fragments of bone, fibrous tissue, etc., should be removed by means of a curette, gouge or chisel. Care should be taken not to injure the periosteum. Portions of the fractured ends should be removed *in situ* by means of a chisel until healthy bone is reached. Frequently, in order to obtain approximation of the fractured ends, it is necessary to remove considerable portions of the bone. In case the tibia or the radius is the seat of the fracture, it is frequently necessary to remove a section of its fellow-bone in order to obtain approximation and to prevent a change in axis at the seat of the fracture. Internal fixation should be made by means of heavy chromicized catgut according to the method given above. The wound should be closed without drainage, and a well-fitting plaster-of-paris dressing applied, which secures perfect immobilization at the seat of the fracture and of the joints above and below the fracture. In this class of cases union takes place more slowly than in recent fractures.

IV. THE OPERATIVE TREATMENT OF SEPARATED EPIPHYSIS AND FRACTURES ASSOCIATED WITH DISLOCATIONS.

The chief difficulty met with in the treatment of separation of the epiphysis is due to the fact that an accurate diagnosis is often impossible, and the condition can not be determined to any degree of certainty by the x-ray, on account of the transparency of the epiphysis to the x-ray. The most accurate results in diagnosis are obtained by examination under anesthesia.

When it is determined by proper manipulation under anesthesia that a displaced epiphysis can not be replaced, or fails to remain in its proper position when reduced, operative intervention is indicated if we wish to prevent bones and joints from subsequently becoming deformed.

Replacement of a displaced epiphysis after aseptic exposure is followed in most cases by union and normal growth of the epiphysis.

TECHNIC OF THE OPERATION.

The operative treatment differs from that used in the treatment of fractures in the adult. The introduction of sutures, and especially of metal and ivory screws, nails and pegs, is often followed by permanent atrophy of the epiphysis and subsequent failure of development of the involved limb. It is advisable in these cases, after exposure of the epiphysis under rigid aseptic precautions, to suture the torn periosteum, and if the capsule of the joint is ruptured, it should also be repaired. After approximation of the epiphysis and suture of the torn periosteum and capsule, the part should be held by an assistant until the operation is completed and the parts immobilized by a plaster-of-paris dressing.

Fractures associated with dislocations have always been followed by considerable deformity and impairment of the joint functions, when treated by non-operative methods. It seems rational that in cases in which the dislocation can not be reduced and the fracture treated at the same time, that recourse should be made to operative intervention. Under aseptic precautions the joint should be exposed, the capsule opened, the head of the bone replaced and the tear in the capsule repaired. If the associated fracture is one that is difficult to treat by non-operative methods, as a fracture of the surgical neck of the humerus combined with a dislocation of the head of the same bone, the fracture should also be exposed and the fractured ends sutured together with chromicized catgut. The part should then be immobilized in a plaster-of-paris dressing. Massage and passive motion may be instituted earlier under this method of treatment, and the chances of securing a movable joint, and absence of deformity will be greater when the condition is treated by operative measures.

V. THE OPERATIVE TREATMENT OF DEFORMITIES FOLLOWING FRACTURES.

The deformities following fractures may consist in (1) shortening; (2) shortening combined with alterations of rotation of the distal fragment; (3) angularity at the seat of fracture; and (4) limitation of motion, due to changes in the normal relations of the joint surfaces. Deformities most frequently occur in fractures of the clavicle; in fractures of the lower end of the humerus; in Colles' fractures; in fractures of the lower end of the femur; in spiral fractures of the tibia; and in Pott's fractures. In the correction of deformities following fractures, depend to a great extent the future usefulness of the patient, and in laborers it is of the greatest importance to leave his skeletal mechanics in as normal condition after the injury as they were before.

TECHNIC OF THE OPERATION.

While some deformities following fractures may be corrected to a certain extent by osteotomy (subcutaneous), or by the resection of a wedge-shaped piece of bone, the best results can only be obtained by exposing the seat of the former fracture and resecting the deformed area of bone. The operation should be performed under aseptic precautions. The site of the deformity should be exposed as detailed above. Care should be taken to separate the periosteum from the bone without tearing it. The section of bone may best be removed with a Gigli chain saw or with a chisel. The plane of section and the amount of bone to be removed will depend on the individual case. In a double bone limb it may

be necessary to remove a section from the fellow-bone, to allow of approximation of the resected surfaces, and to prevent angularity at the seat of the fracture. This, of course, produces some shortening of the limb, but it is preferable to angular deformity. An intact periosteum may, however, fill in the gap between the resected ends, thus not necessitating resection of the fellow-bone. As frequently happens, however, the periosteum is destroyed to a certain extent at the time of the injury, and has been replaced by fibrous tissue, so that in this event regeneration from the periosteum may not occur, or at best it will be greatly delayed. In patients in whom the element of time is a consideration, resection of the fellow-bone is advocated. After resection, the ends may be held approximated by means of heavy chromicized catgut. The further technic is the same as that of recent fractures.

(To be continued.)

FURTHER STUDIES ON STREPTOCOCCUS INFECTIONS.*

GUSTAV F. RUEDIGER, M.D.
CHICAGO.

About two years ago Dr. Weaver and I¹ showed that the blood serum from patients with scarlet fever has no streptococcal power during life in any stage of the disease. Through the researches of Lemoine, Slawyk, Hektoen and others we know that streptococci occasionally are found circulating in the blood of these patients and that the patients in whose blood cocci are found often make an uneventful recovery. Jochmann,² however, is of the opinion that the prognosis is very bad when streptococci are found in the blood.

What is true of scarlet fever may equally well be said of tonsillitis. Here, too, streptococci may invade the blood stream, but, in spite of this fact, the patient may make a rapid and satisfactory recovery.³

In erysipelas and in many wound and puerperal infections the tissues are invaded by virulent streptococci, but in a great majority of these cases the organisms disappear sooner or later and the patients make a complete recovery.

We know that normal human serum has no streptococcal powers. Hence, the disappearance of the cocci from the blood and tissue can not be explained by assuming that the serum loses something during the height of the disease, but regains this substance as convalescence sets in and thus destroys the cocci. It is evident, therefore, that we must look for some other agent than the serum alone to account for the disappearance of the cocci from the blood and tissues during convalescence. According to Metchnikoff, Denys and Leele, Bordet, Marchand and others,⁴ this agent is found in the phagocytes. This view has not been universally accepted, although experiments show that it explains the facts better than any other theory that has been advanced. In a previous paper⁴ I was able to show that the

leucocytes are the most important, if not the only, factor concerned in the destruction of streptococci in the body of infected rabbits and guinea-pigs. The view was expressed there that in man also the leucocytes play an important rôle in combating infection by these organisms, although not much work had been done on human infections.

In this paper are set forth the results of further studies of streptococcus infections in human subjects in the hope of determining just what factors are concerned in the destruction of the invading cocci, and an attempt is made to analyze more fully this phenomenon. In all instances where blood was used it was drawn from the vein at the elbow by means of a Luer syringe and defibrinated by gently whipping with a sterile wire. If the defibrinating is carefully performed not a very large proportion of the leucocytes are destroyed. In the experiments each tube contained from 0.8 to 1.0 c.c. of blood or serum which was inoculated with one loopful of streptococcus culture and two loopfuls from each tube were plated in glucose agar at intervals. The tubes were always kept in the incubator at 36 C. When highly virulent organisms were used 0.3 to 0.4 c.c. of defibrinated rabbit blood was added to each tube of melted agar to facilitate the counting of colonies, which often are very small if no blood has been added.

Table 1 shows that, although human serum *in vitro* is a good culture medium for streptococci, normal defibrinated blood has a slight streptococidal power. Occasionally we may find a sample of normal blood which destroys many non-virulent streptococci, but the virulent organisms usually multiply in this blood.

TABLE 1.—THE EFFECT OF DEFIBRINATED NORMAL HUMAN BLOOD AND HUMAN SERUM ON STREPTOCOCCI.

B104	IIa	76	55	510
B104	III	1800	2800	Many
B104	IV	1600	3000	Many
B104	V	500	600	300
381	VI	2000	2300	Many
300	Serum IV	1400	2000	Many
298	Serum VII	1700	2500	10000

Source of streptococci: Strains, 298, 300 and 381 from heart blood of scarlet fever bodies, postmortem. B104 from an abscess in guinea pig; 298 and 300 are not virulent; 381 and B104 have been passed through rabbits and are highly virulent.

Table 2 shows that defibrinated blood from patients suffering from an acute infection has a much greater destructive effect on these organisms than has normal blood.

In these infections the leucocyte count is usually somewhat increased, and it seems that the streptococidal power of the blood *in vitro* is roughly proportional to the leucocyte count. That is, the higher the leucocyte count the greater will be the streptococidal power of the blood. This is a general rule, to which there are, however, a few exceptions, as will be pointed out later. The virulent organisms frequently multiply in these bloods unless the leucocytosis is very high. In no instance could a streptococidal power of the serum alone be detected. It might be objected that we are not dealing here with an actual destruction of cocci, but that the decrease in the number of colonies on the plates is

due to adherence of the cocci to the leucocytes. This objection is ruled out by the fact that the twenty-four-hour plates from tubes containing blood with a high leucocytosis are very often sterile or nearly so.

It has been thought possible that the serum during the course of an infection which terminates favorably might acquire streptococidal properties for that particular race of streptococci which is responsible for the infection, while at the same time it had no such properties for other races of these organisms. Three strains of streptococcus were, therefore, isolated from erysipelas patients and the serum of each patient tested on the corresponding organism. All of the patients made a satisfactory recovery, but at no time could streptococidal properties be demonstrated in their serum. The defibrinated blood, on the other hand, killed many of the homologous and other organisms as long as there was a high leucocytosis.

We know that there is an intense local reaction in the localized streptococcus infections, and it has been thought by some that there may be lysis of cocci by the inflammatory serum in these areas. It is difficult to confirm or refute this theory on account of the difficulty of obtaining inflammatory serum in the same condition as it is found in the tissues. As it is not uncommon to find blebs of considerable size on the affected parts of erysipelas patients, the fluid from these blebs was taken as the nearest approximation to the inflammatory serum. This blister fluid from several cases of erysipelas was tested for streptococidal properties, but gave negative results.

The importance of a high leucocyte count in the destruction of streptococci by blood is clearly shown by the following experiment:

EXPERIMENT 1.—Ten cubic centimeters of blood were drawn from the vein at the elbow of an erysipelas patient and carefully defibrinated. One cubic centimeter of the defibrinated blood, which contained 9,800 white corpuscles per cubic millimeter, was put into a small test tube, inoculated with one loopful of virulent streptococcus culture and two loopfuls of the inoculated blood, plated at intervals. The remaining eight cubic centimeters were centrifuged and the serum drawn off. We know that the uppermost stratum of centrifugated corpuscles contains a high percentage of leucocytes, because they are thrown down less easily than the red corpuscles. This stratum was therefore drawn off with a sterile pipette and mixed with a small quantity of serum. The resultant mixture contained 17,200 leucocytes per cubic millimeter. One cubic centimeter of this "suspension of leucocytes" was introduced into a small test tube, inoculated, and plates made as before. To complete the experiment one cubic centimeter of the clear serum was put into a small tube, which was likewise inoculated, and plates made at intervals. This experiment was also performed with normal blood and a non-virulent streptococcus. The plates were incubated for twenty-four hours, and the colonies that developed on each were counted with the results shown in Table 3.

TABLE 3.

Strepto- cocci.		Leucocyte count.	Colonies on Agar plates.		
			Im- med.	2 to 3 hrs.	5 hrs.
B104	Erysipelas blood.....	9800	390	168	350
B104	Suspension erysipelas leuc.	17200	360	58	21
B104	Erysipelas serum.....	4400	200	360	1100
298	Normal blood.....	4400	1650	690	315
298	Suspension normal leuc.....	6600	1000	420	62
298	Normal serum.....		1700	2500	10000

The table shows that both strains of streptococcus used multiplied in the cell-free serum; that the defibrinated blood destroyed many of the non-virulent and some of the virulent cocci, and that the "suspension of leucocytes" destroyed more cocci of either strain than the defibrinated blood. The only difference between the defibrinated blood and the suspension of the leucocytes lay in the fact that the latter contained nearly twice as many leucocytes as the former.

The fact that the streptococcal power of the blood is dependent on the number of leucocytes it contains per cubic millimeter has also been demonstrated by a second experiment.

EXPERIMENT 2.—Shortly after a patient's admission into the hospital, 3 c.c. of blood was drawn from a vein at the elbow and defibrinated. The leucocyte count at this time was 11,000. The blood was divided equally among three tubes, and each tube was inoculated with streptococcus culture and two loopfuls from each were plated at intervals. Shortly after drawing the blood, the patient was injected under the skin of the back with 10 c.c. of an antistreptococcus serum. This brought about an increase in the leucocytosis⁶ up to 15,000, five hours after the injection. Three c.c. of blood was again drawn from the vein at the elbow and its effect on streptococci tested as before. The results of the experiment are shown in Table 4.

The blood drawn after the injection of the serum, when the leucocytosis was high, has a greater streptococcal power than that drawn before the injection. It would not be safe to conclude that this difference in the streptococcal power is due entirely to the difference in the leucocyte count. Some of it may be due to an antitoxic or opsonic action of the serum or to a stimulation of the leucocytes. This supposition loses most of its

force when we consider the fact that the addition of from 1 to 5 per cent. of antistreptococcus serum to defibrinated blood in vitro does not increase its streptococcal power, as shown by Dr. Hektoen and myself.

381	Blood before injection.....		100	500	Many
300	Blood 5 hours after injection.....	15000	1300	44	...
B104	Blood 5 hours after injection.....		412	246	600
381	Blood 5 hours after injection.....		150	270	3000

Wright and Douglas have shown⁶ that phagocytosis takes place only after the bacteria have been sensitized, that is, have been acted on by the opsonin of the serum. There is no phagocytosis in a suspension of washed leucocytes in NaCl solution or in heated serum, regardless of the number of untreated bacteria that are added. This work has been confirmed and extended by Hektoen and Ruediger⁷ and by Bulloch and Atkin.⁸ In view of these facts there should be no reduction in the number of streptococci in a test tube containing a suspension of washed corpuscles in salt solution or in heated serum, and the following experiment shows that such is the case:

EXPERIMENT 3.—Ten c.c. of blood was drawn from a vein at the elbow of a scarlet-fever patient, defibrinated, centrifugated and the serum drawn off. The corpuscles were washed twice in a large amount of NaCl solution, and 0.5 c.c. of the centrifugated corpuscles placed into each of three small tubes containing 0.5 c.c. of normal serum, 0.5 c.c. of heated serum (58 degrees for one-half hour) and 0.5 c.c. of salt solution, respectively. The tubes were inoculated with one loopful of streptococcus culture, and two loopfuls from each were plated at intervals with the results shown in Table 5.

TABLE 5.

Strepto- cocci.		Colonies on Glucose Agar Plates.		
		Im- med.	5 hrs.	24 hrs.
300	Washed corpuscles + serum.....	1500	7	21

300	Washed corpuscles + NaCl solution...	1700	3500	Many
300	Serum.....	1200	1400	Many

The importance of opsonin in the destruction of streptococci is further shown by the fact that the defibrinated blood from two obstinate cases of post-scarlatinal nephritis had no streptococcal powers, although in one of these cases the leucocyte count was 14,000. When the blood from these patients was centrifugated and the corpuscles suspended in serum from a patient who was convalescent and had no nephritis, the resultant suspension had a small degree of streptococcal power, as shown by Table 6.

TABLE 6.

Strepto- cocci.		Colonies on Agar Plates.		
		Im- med.	2 hours.	5 hrs.
298	Convalescent blood.....	800	450	14
298	Nephritis blood.....	720	1900	6000
298	Nephritis corpuscles + conv. ser....	850	500	540
298	Conv. washed corp. + neph. ser....	725	600	61

The interesting fact came to light in these experiments that the combination convalescent washed corpuscles

8. Proceedings of Royal Soc., 1905, vol. lxxiv, p. 379.

5. I am indebted to Dr. Tunncliffe for the leucocyte counts and the injection of the serum.

cles plus nephritis serum has nearly as great a streptococidal power as the defibrinated blood from the patients without nephritis. The corpuscles were washed twice in a large amount of NaCl solution which is usually sufficient to prevent phagocytosis in a suspension of corpuscles in NaCl solution. It is not likely, therefore, that the washing had not been carried far enough. But the results of these experiments seem to indicate rather that the leucocytes as well as the serum from these nephritis patients have undergone some change which renders them less efficient in the destruction of bacteria. In fact, it would seem that the leucocytes have suffered more than the serum. Whether or not these facts may serve to throw light on the cause of some of the terminal infections can not be determined at this time.

It is an interesting question whether the opsonin is increased or not during the acute infections. Normal leucocytes in normal serum take up large numbers of cocci; hence, it is difficult to determine if leucocytes in erysipelas serum, for instance, take up more cocci than those in normal serum. This question had, therefore, to be approached in a different way.

EXPERIMENT 4.—Two sets of tubes were made and 0.2 c.c. of washed corpuscles introduced into each. To one set of tubes were added falling quantities of normal serum and to the other set falling quantities of erysipelas serum. The contents of each tube were made up to 0.4 c.c. with NaCl solution, and to each tube was added 0.4 c.c. of a suspension of streptococci. The tubes were incubated for one hour at 36 C., smears were made and the average number of cocci in each leucocyte determined by counting those in 30 leucocytes. The results are shown in Table 7.

TABLE 7.

Normal serum.	Phagocytosis.	Erysipelas serum.	Phagocytosis.
0.2 c.c.	13.5	0.2 c.c.	1.1
0.1 c.c.	9.4	0.1 c.c.	11.2
0.05 c.c.	6.7	0.05 c.c.	8.2
0.025 c.c.	4.7	0.025 c.c.	6.9
0.012 c.c.	2.2	0.012 c.c.	4.3

This experiment indicates that there is a slight increase of opsonin in the erysipelas serum as compared with normal serum. A similar increase of opsonin has been noted by Wright and Douglas⁹ after treating with their staphylococcus vaccine a person afflicted with furunculosis. A diminution of opsonin in persons subject to attacks of furunculosis, syphilis, etc., has also been observed by these investigators.

CONCLUSIONS.

1. Human serum does not acquire streptococidal properties during the course of a streptococcus infection.
2. The blister fluid from erysipelas patients has no streptococidal powers.
3. Defibrinated human blood has a streptococidal power which, with few exceptions, is roughly proportional to the leucocytosis.
4. The destruction of cocci in the defibrinated blood is brought about by the leucocytes, but before this can be accomplished the cocci must be acted on by the opsonin of the serum. There is no phagocytosis and hence no destruction of unsensitized cocci by washed leucocytes.
5. The opsonin is increased during the course of an attack of erysipelas.
6. In an attack of acute nephritis the opsonin is diminished, but the leucocytes also undergo a change which renders them less effective in the destruction of streptococci. This fact may serve to throw light on the cause of many terminal infections.¹⁰

DISCUSSION.

Dr. M. J. ROSENAU, Washington, D. C., said that the results which Dr. Ruediger has obtained from his work on streptococcus infections have more than theoretical significance, for it is plain that this line of thought must eventually give practical results in the prevention and cure of the virulent infections caused by the various strains of streptococci. He said that Dr. Ruediger's paper clearly shows that the destruction of streptococci in the body is not the result of the serum or inflammatory fluids alone, but bears a direct relation to the number of leucocytes. This work gives a deeper insight into the process of phagocytosis and the part played by the leucocytes, especially in their relation to streptococci. Dr. Rosenau said that as a further confirmation of the opsonins described by Wright, it is a distinct advance in our knowledge of immunity.

PAROXYSMAL TACHYCARDIA: ITS RELATION TO EXOPHTHALMIC GOITER.

CARL C. WARDEN, Ph.B., M.D.

BATTLE CREEK, MICH.

It is my wish to emphasize the relationship apparently existing between certain cases of paroxysmal tachycardia and exophthalmic goiter, and to suggest that a more thorough examination of such cases may serve to trace the connection in a considerable proportion of instances. The more I see of this symptomatic disturbance, the less inclined am I to regard it as a definite entity or deserving of special caption in the category of disease. A superficial survey of the literature shows some 160 references to the subject, and as yet there has been no opportunity to observe what proportion of the cases are regarded by their reporters to have been due to exophthalmic goiter, though it is apparent that the percentage is small. It is hoped that a thorough resumé of the subject may be embodied in a future note. The present communication is actuated by two recent cases in my practice, of which full histories and notes to date follow:

CASE 1.—*History*.—Mrs. C., aged 38, married 16 years; has two children, the younger of whom is 8 years old. No miscarriages. Puberty at 12. Menstrual periods have always been accompanied by pain, which was relieved when the flow became established. Ordinary diseases of childhood, but no specific or rheumatic history.

Present Sickness.—The patient complains of constant pain in the legs, mostly at the knees, especially the right knee. This pain extends upward at times, and again downward, is dull in character but liable to acute phases, at which times there is apt to be locking of the right knee joint. There is a limp in walking which has been noticeable for twenty years. She also complains of hemorrhoids. The chief symptom and the one for which she seeks relief is periodic palpitation of the heart with hurried breathing, and some pain in the chest at such times. The attacks come on without warning, but usually follow fatigue or excitement. There is no regularity in occurrence, nor association with the menstrual period. Of late she has had one each month, lasting from two to ten hours. The duration of the complaint covers a year's time.

In the family history there is nothing to note beyond rheumatism in the father and "an asthmatic complaint" in the mother.

Examination.—Patient is above average height, well nourished, weight 125 (below her normal); the skin is soft, smooth and elastic, and the exposed portions are somewhat bronzed; the palms are moist, the fingers broad but not clubbed. Pulse 114, soft, low tension, fairly full. There is apparent and palpable enlargement of the thyroid body of which she was unaware. Circumference of neck over greatest prominence, 13½ inches. Lungs negative; expansion is free and symmetrical; epigastric angle acute. Apex beat is in the sixth space inside the mammary line. Dullness one finger breadth to right of sternum. Heart sounds are distinct and clear. A rough sys-

9. Proc. Royal Soc., Sept., 1904.

10. I wish to thank Professor Hektoen for many suggestions, and the Internes of Cook County Hospital for courtesies.

tolic murmur is present over the base and is not transmitted. Epigastric pulsations are apparent and the systolic murmur is heard here, but not elsewhere in the vessels.

Liver, stomach and splenic outlines are normal in size and position and the abdomen generally is negative.

The grasp is firm, stronger in the right hand. Supinator jerks diminished on both sides. There is tremor, fine, about seven to the second, most noticeable in the extended fingers, but palpable in the thighs on shifting the body weight from one leg to another. The knee joints are normal and symmetrical to inspection and palpation. Knee jerks are exaggerated. Normal flexor response on both sides. There are no disturbances in tactile or thermal senses.

The back shows the remains of an old kyphoscoliosis. She wore a brace for this condition for four years, but for the past two years has had no trouble.

The mucous membranes show no bronzing. The pupils appear large, but are equal and react to light and accommodation. There is no Stellwag or von Graefe sign or exophthalmos.

Pelvic examination shows the uterus in good position and freely movable, a tenacious discharge coming from a large and eroded os. The fundus has a depth of 3 3/4 inches and the interior is somewhat granular. Rectal examination shows some hemorrhoidal tissue, but not exuberant, and a few anal tags.

Lavage shows a normal gastric secretion. Blood; erythrocytes, 3,400,000; hemoglobin, 70; leucocytes, 8,700. Urine, total, 24 hours, 1,060 c.c.; acid; sp. gr., 1016; urea, 1.7; no albumin or sugar, anophosphorus urates, mucus and vaginal epithelia.

Diagnosis and Treatment.—A diagnosis of exophthalmic goiter was made and the patient put on the following treatment: Graduated tub baths, 85 to 105 degrees, three times weekly, alternating with salt glows and alcohol rubs, with gentle massage to promote a healthy skin function; nutritive, full, easily assimilable diet, daily exercise out of doors; the application of the direct current, 20 milliamperes, the anode over the thyroid and the cathode on the cervical spine, for ten minutes three times a week; liquor potassii arsenitis, 2 mm. t. i. d. Treatment was begun April 25, 1904. The pulse ranged daily from 100 to 115.

First Attack.—On May 8 at 8:30 a. m. a paroxysm began and continued until 4:30 p. m. The patient took the position of greatest comfort for her, dorsal with a very low pillow, and lay quietly throughout the attack. The skin was flushed, moist, the expression good, the pupils dilated and sluggish to light and accommodation. The pulse was soft and weak and many waves failed to reach the wrist. The cardiac impulse covered an area the size of the palm and was observed to be forcible and sharp. The sensation conveyed to the hand was of a machine tapping from below. At a distance of a foot from the chest the quick systolic thumping of the heart could be distinctly heard. With the stethoscope the first sounds were loud and ringing, the second almost in abeyance everywhere. With the hand or the stethoscope the rate of the tachycardia could easily be noted, ranging from 190 to 240 throughout the paroxysm and recorded every hour. She complained of rather severe pain, also paroxysmal, and not related to the frequency of the heart, in the heart area radiating to the back. Once or twice during the day she took nourishment.

About 4 p. m. the patient's condition was as follows: Sweating and diuresis (the latter 1,120 c.c. since 8:30 a. m.), moderate cyanosis of ears, lips and fingers, expression one of great fatigue, pupils unchanged, pain intermittent and severe, heart rate 198. Heart dullness extended two fingers to right of sternum, the veins of the neck pulsating and full. Heart sounds weak and flapping. Respirations 20 and sighing.

At 4:30 p. m. the cessation of the attack was marked by a fall in respirations to 20, a general feeling of betterment, absence of pain and diminution of sweating. The behavior of the heart was most interesting. Now and then with the weak beats came a strong one, and occasionally a strong beat would take the place of the two or three weak ones, giving a curious arrhythmia and force wave. The strong beats all sent waves to the wrist. Gradually the strong beats gained supremacy over the weak ones until the ratio became about 3 to 1, and from then on there was a widening ratio until within an hour the heart settled down to steady work at 105.

At 9:30 a. m., after having made use of such therapeutic measures as stretching vagi by posture, pressure on them, holding the breath, iced and hot drinks, heat and cold to the precordia, there were given digitalin 1/100 gr. and ergot 1 dram hypodermatically; at 11:30 morph. sulph. 1/4 grain; at 2 p. m. spartein 1 grain; at 4 p. m. morph. sulph. 1/2 grain and digitalin 1/50 hypodermatically. We were under the impression that the last medication was effective, but were not unmindful of the fact that the paroxysms not infrequently terminate without medication.

The following day the patient was out of bed and feeling about as well as usual. From this time until June 5 she improved generally. The tachycardia diminished from 105 to 110 to 90 to 96 and the neck measured 13 inches. She continued taking arsenic and was put on the infusion of digitalis, half an ounce t. i. d., gradually diminishing it as the tachycardia grew less pronounced.

Subsequent Attacks.—June 5, however, she had another seizure, commencing at 10:30 a. m. and ending at 3 p. m. At the outset she was given digitalin 1/50 grain, and this was repeated at 2:30 p. m. The attack was much the same as the preceding, but with less pain. The highest heart rate was 240. There was less sweating and no cyanosis. In the next two months the patient was without attacks. She then passed from immediate observation. Since then there have been seizures of moderate severity, but a recent communication, June, 1905, tells me that she is much improved. What medication, if any, she is having is not made clear, but at last accounts she was taking a combination of strophanthus, digitalis and nux vomica tinctures, 5 minims each, t. i. d.

CASE 2.—History.—Mrs. P., aged 40; has three children, youngest 16, no miscarriages, had difficult labors, with lacerations each time, which were repaired. Menstruation regular, no pain, flow slight and becoming more so; duration one day.

Present Sickness.—She was well up to four years ago, when she began having palpitation of the heart, accompanied by shortness of breath at irregular intervals, the attacks coming on suddenly and lasting from one to five hours. Later she began to have pain with the attacks, severe, in the cardiac regions and neck, radiating into the left arm. She states that her nervousness in general has increased. The longest interval between attacks has been three months, and on the other hand she has had as many as three in one month. Occasionally she is able to foretell oncoming paroxysms by increased nervousness; at other times they appear without warning. During the attacks she sits on a chair or the bedside, or lies back on the pillows between the exacerbations of pain. The pain is severe but not overwhelming, and is relieved by pressure. Between attacks she feels and looks well. The appetite is excellent, there is no constipation, and she sleeps well.

In February of 1905 she had right lobar pneumonia and made a good recovery. Her personal and family history are otherwise negative.

Examination.—Height 5 feet 2 inches; weight 130. Fairly nourished, muscles somewhat flabby, skin dry and scaly. Slight bronzing in the posterior cervical regions and a muddy color of the face. The neck measures 13 1/2 inches. The thyroid body is not apparent on inspection, but can be made out by palpation. The thorax shows the scar of an old abscess in the left breast. A thickened pleura and impaired resonance over the upper right lobe mark the site of the pneumonia area.

The heart is enlarged to the left, the apex lies in the sixth space just inside the anterior axillary line; the sounds are clear; the pulmonary second sound is accentuated. The right heart is not demonstrable. Pulse 105, respiration 20, temperature normal. The abdomen is negative. The pelvic examination shows the repairs, and a slightly enlarged but otherwise normal uterus.

There is no exophthalmos apparent, but occasionally there is observed von Graefe's sign. The pupils are slightly dilated and sluggish to light, but react briskly to accommodation. Muscular power is fair.

There is tremor, fine (6 to 8), particularly noticeable in the extremities, but present in all muscles that are called forcibly into play. The deep reflexes are exaggerated. The sensory apparatus is keen. There are no hysterical stigmata.

Urine, 1,420 c.c., acid, sp. gr. 1.019; urea, 2.1, no albumin or sugar.

First Attack.—Blood: Reds, 3,125,000; hemoglobin, 62 per cent.; whites, 6,400. On the night of May 17, 1905, she had a paroxysm, commencing at midnight. She was seated in a chair, her posture of greatest comfort. The heart rate was 220, respirations 30, the pain was endurable and not constant, her face was flushed, the skin moist, and the kidneys were active. Before I saw her she had already taken strychnin, 1/50 gr., and digitalis, 1/100 gr.

This seizure occurred before I had examined the patient, and when I reached her side her husband told me his physician had said she had angina pectoris. Without waiting to examine her with any degree of care, I gave her hypodermically, at 12:30 a. m., nitroglycerin, 1/100 gr. Between that time and 1 o'clock, when the paroxysm ceased, I was able to observe her more closely and to recognize the nature of the disturbance. I am by no means convinced that the injection availed whatever, yet I am certain that it did the patient no harm. It was the slightest paroxysm she had ever had. The character of the heart's action, its behavior during the continuance and decline of the seizure and the general features of the circulatory disturbance were so similar to the case previously outlined as to require no further description.

Subsequent Attacks.—The following day she was apparently as well as ever. The patient went to her home, at some distance from the city, and did not return until June 15. The multiplicity of her household duties and the fatigue of travel made her very nervous and she was able to foresee another paroxysm, which eventually appeared at 7 p. m. on June 19 and continued for three hours. Before I reached her she had taken, as usual, the strychnin and digitalin. I promptly gave her nitroglycerin, 1/100 gr., with no damage and no relief. She was then given morphia sulphate, 1/4 gr., and digitalin, 1/100 gr., at half-hour intervals for three doses, when the pupils indicated their discontinuance; with this medication were employed all the customary physiologic remedies. There was no cyanosis or dilatation during the attack and the course was generally characteristic. The morphia controlled the pain, but rendered the patient very restless and caused considerable nausea and vomiting after the subsidence of the paroxysm. A few days later the patient was put on the tinctures of digitalis, strophanthus and nux vomica, of each 5 minims t. i. d., and a pill of arseniate of iron, 1/12 gr., after meals, and was treated three times weekly with the direct current of 10 milliamperes for 15 minutes, the anode to the thyroid body and vagi and the cathode to the cervical spine. This treatment was given daily after the first fortnight.

July 5 the neck measured 12 1/2 inches, with no change in body weight.

July 7 there occurred a curious variation of conditions. Following a regimen of the cardiac tonics above mentioned and a rather prolonged seance of electrization, the patient had a headache, neuralgic in type, gradually increasing in severity, worst at the occiput. The pupils became moderately contracted and sluggish both to light and accommodation. The pulse was full, hard, of high tension, 60 beats to the minute. The attack persisted for 24 hours. On July 9 the pulse rate had returned to 100 and was soft and compressible.

July 16 and 17 the patient had premonitions of a seizure. There were slight momentary attacks of tachycardia, the pulse being 200, with occasional pains in the chest.

At 5 p. m., July 18, a paroxysm came on. The pain and flushing were pronounced, diuresis was marked, the catheter being called into use hourly. In this attack, in addition to the customary medication, there was given atropin, 1/50 gr., but with no effect whatever.

August 4 was the date of the next seizure. It was 2 hours in duration, with all symptoms characteristic.

August 21 occurred the last paroxysm up to the present time, October 10. It was characterized by pain, less severe than usual, and absence of extreme tachycardia. At its height the pulse rate did not exceed 120.

At the conclusion of the patient's residence under my care, September 1, her weight was 140, her general condition excellent. The neck measured 12 3/4 inches. The tremor was much

less evident. A recent communication from her informs me that she has continued to do well and is feeling much improved.

I was so fortunate as to have both these cases under immediate and constant observation, personally and by competent nurses. The cardiac rate was taken invariably at the heart, for often at the wrist the pulse was uncountable and occasionally unappreciable. Sources of error have been allowed for. The counting was done by the hand over the precordia, by stethoscope and by flags on the chest wall. Considerable doubt has been expressed by not a few of my colleagues as to one's ability to count 240 to the minute. The average watch ticks 5 to the second, or 300 to the minute, and is readily countable, particularly if taken by tens. Some practice is necessary in recording observations in tachycardia by any method other than instrumental. The rather exceptional advantages afforded for observation in the two cases submitted have made me confident that the records are approximately exact. Of late good results have been obtained, in some instances, by treatment with thyrodoctine. I have had no personal experience with the remedy.

THE PRESENT STATUS OF THERAPEUTICS.*

W. G. MOORE, MD.

ST. LOUIS.

When I was a student at Jefferson Medical College one of the members of its distinguished faculty made the assertion that he "could encircle the globe and cure more diseases with four remedies than could be cured with all the balance of the materia medica." The four remedies named were quinin, opium, mercury and iodid of potassium. None will deny the therapeutic power of these drugs nor the vast scope of their usefulness. Indeed, the more we consider the statement the more we question whether it does not hold good to-day, notwithstanding that it was made more than twenty-five years ago.

We are forced to ask ourselves whether therapeutics has been standing still while pathology, bacteriology, chemistry, diagnosis and surgery have rushed into such prominence as to challenge the admiration of all who keep pace with the progress of the sciences, and while preventive medicine and sanitation, which stand alone in achievement for the welfare of men in every walk of civilization, have made habitable the squalid tenements of the dependent poor, protecting the middle and moneyed classes against the results of their own follies in social life, making possible the great commercial undertakings of nations, and encompassing the most remarkable saving of life from disease in the latest and most destructive war of modern times?

It is not my purpose to discuss the therapeutic action of individual remedies nor to rehearse what has been written concerning the numberless new remedies which are constantly forced on our notice through the energy of the army of manufacturers, all of whom claim special therapeutic advantages for their products, and whose assertions, if true, would leave nothing to be desired in remedial agents. This multitude of new remedies comes to us like the leaves of the forest—they hold the attention for a season, then fade, die and pass away. Many of them prove totally worthless, but they disappear only to be replaced by others of a similar kind, going to a similar fate.

The effect on the status of therapeutics is to make con-

*Read before the Missouri State Medical Association at Excelsior Springs, May, 1905.

fusion worse confounded and to engulf the real object of the therapist in hopeless chaos. It is my desire to bring this condition of things to the minds of practical men and to ask their aid in bringing some sort of order out of this evident confusion.

There was a time when the U. S. Pharmacopœia and the U. S. Dispensary were the guides to what should and should not be considered as real therapeutic agents.

Admitting their shortcomings, and these were undoubtedly many, they were the channels through which we might obtain that which was best, since they represented with some sort of system the true worth of drugs.

Times are different now. I believe it is safe to assert that 90 per cent. of all prescriptions written call for non-official drugs that have been put on the market by those averse to the best interests of therapeutic progress.

Manufacturers are supplying us with thousands of different remedies, but how many practitioners can name fifty or even twenty-five of them? How many remedies compose your medical armamentarium? What do you know concerning the remedies you are using and from what source have you learned it? An agent, often a non-medical man, comes to your office, displays the wares that you are asked to prescribe and presents pamphlets, catalogues and dogmatic clinical assertions from men of whom you have heard nothing, and consequently who are not known by you as men in whose judgment you should place confidence, and yet you are expected to recognize them as authorities to point the therapeutic way. It is in this way that you are asked to use these remedies—of whose composition you know nothing—on the sick who have entrusted themselves to your professional care.

In the face of such conditions is it any wonder that the therapeutic sensations of to-day are forgotten in their grave of oblivion to-morrow? Is it to be wondered at that the profession is overrun with therapeutic nihilists who know nothing of curative methods and are content to grope about in the mass of new remedies, hoping to find a cure for pneumonia, phthisis and typhoid fever, and are willing to cast their fortunes with the commercialists and to adopt their easy fashion of labeled tablets, which tell the diseases—and they are many—in which they are to be used, the dose, and how to use them?

I am far from saying that no good remedies can reach physicians in this way. My plea is for some means to get and to hold fast to that which is good, from whatever source it may come, and to be delivered forever from the worthless mass which pours on us to our disgust. If a manufacturer evolves a preparation that is a real improvement let him have the credit and the profit, so long as everything known about the remedy is made public and that no mystery attaches to it, and no ridiculous claims are made for it as a therapeutic agent.

Let the medical profession demand that there be some recognized method of proving the therapeutic value of every agent offered to it, and that the sign manual of such proof shall accompany it. Then, and not till then, will the shameless business for which these remedies are primarily responsible cease to be. I had the honor to suggest in a public address a year ago that the legislature be petitioned to pass a law requiring every package containing medicine to be sold or given away in the state of Missouri to have a label setting forth the exact contents. I reiterate, with deeper conviction than ever, that it is the duty of the state to protect its people against the infamies of "patent medicine" vendors, who are doing more harm and causing more ruin

than any disease which is fought and quarantined by the State Boards of Health. How much more should we demand absolute non-secrecy about the preparations we are to use on the sick, and also honesty in their exploitation.

With the gallant band of our professional brothers now members of the legislature such a bill would find a sufficient number of Davids to slay the Goliaths of this industry.

I stated some time ago that the medical profession itself is primarily responsible for the existing condition of things. Physicians have allowed themselves to become animated billboards on which have been written the advertisements of unscrupulous scamps, and then have been made to parade their asininity and poverty before the public, while the compounder of some whisky, cocaine, morphin or iron preparation or coal tar and caffeine powder grows into a money magnate who laughs at our gullibility and then stands in the lobby of our legislatures a bulwark against right and justice.

Again the responsibility of the profession is shown in the license allowed medical journals which are absolutely the creatures of physicians and should be under their control. If no physicians patronized medical journals which are under the control of nostrum manufacturers their days would be few and full of trouble. With the great number of struggling orphans in the journalistic world it is a matter of necessity with many of them that they have advertisements—good if they can get them, but bad if they must have them. The wealthy parasite alone referred to knows their necessity and commands their columns to send broadcast to the world the debauching mixtures he has concocted, and the poor, honest, unsuspecting physician continues to patronize his worst enemy and to obey the scriptural injunction by turning the other cheek to be smitten.

If this shameful business were confined to the weaklings of the medical press it might be viewed with some sort of compassion, but with no justification of the wrong, but when it finds place in the powerful metropolitan journals, those by which we are to be judged, and when the advertising stuff on either side of the reading matter makes the latter look like the ham in a poor boy's sandwich, then, my brethren, "the offense is rank and it smells to Heaven."

Take this, for example, from a reputable journal: "Antiphlogistine is now the standard remedial agent for pneumonia, pleurisy and bronchitis, primary or secondary to la grippe or any other disease." It then proceeds to recite ten reasons why this is true, two or three of which will convince any scientific mind of the unimpeachable truth of these remarkable axioms: 1. "Because antiphlogistine draws the blood to the surface—bleeds but saves the blood." 2. "Antiphlogistine by reflex action contracts the pulmonary vessels, thus depleting the lungs into the dilated superficial capillaries." 3. "Antiphlogistine relaxes the muscular and nervous systems, thereby tending to induce sleep." I ask you to ponder well these profound scientific truths and the reason for their enunciation will become clear as mud.

The chests of pneumonia patients all over this land in this enlightened age are being smeared with this stuff because the benevolent proprietors tell physicians to do it. Commercialism is paralyzing individual thought in therapeutics and making it the subject of ridicule by sensible men.

Think of Osler making a careful diagnosis of pneumonia and then solemnly ordering the patient to be encased in "the standard remedial agent" because he knew

it to be a "blood drawer," a blood saver, a hypnotic and anodyne all in one, and then instructing the nurse in the event that the Congressman's catarrh should grow worse or evidences of heart failure manifest themselves, to resort at once to full doses of peruna until decided evidence of alcoholism became manifest. If he followed this therapeutic trend he would be in line with a large number of men now claiming to be regular practitioners of medicine. Is it to be wondered that so many neuropathic inferiorities prefer to be healed by "absent treatment?"

Here is another gem found in a medical journal, which, before its "consolidation," declared it would permit no irregular advertisement to defile its pages. Under scarce head lines the word catarrh is emblazoned over the statement that "germiletum is really a specific in catarrh!" "Germiletum is also unexcelled in eczema!" You will notice that a specific has been found for that most widely spread affliction, catarrh, as well as the seven-year itch, for one of the members of this society says in a testimonial of this new-found panacea: "Nasal catarrh, which has long been an odium of medicine, may now be combated successfully by the alkaline antiseptic germiletum."

A journal which has, or claims to have, "the largest circulation of any medical publication in the world," and whose editor, I am informed, is not even a graduate of medicine, but an undergraduate of an eclectic college, has for years done everything tending to cheapen and to degrade the medical profession, while it enriched its editor, is now claiming through a smart woman canvasser to be the best field for communications from medical men, "only professors in medical colleges," however, "because it reaches the largest audience in the medical world."

The character of this publication can be best understood when you know that it has persistently decried the uses of diphtheria antitoxin and lauded the antiseptic washes, gargles and so on manufactured by its opulent owner and publisher.

This shrewd canvasser called attention not only to the articles written by, but to the photographs of, the celebrated eastern luminaries who are to enlighten the benighted brethern of the south and west, to be found in this journal. It is painful to relate how many good but unwary men fell into the trap and became endorsers of this cheap and blatant sheet. It is gratifying, on the other hand, to know how many men refused to entertain the idea at all.

So long as the columns of medical journals can be made subservient to the commercial interest of proprietary medicine venders and quacks just so long will therapeutics of the scientific order be relegated into oblivion to the disgrace of physicians.

Let us devoutly hope that the pages of our own state journal will be kept free from quack and proprietary exploitation. If we cannot keep it alive without it, then let it die.

Lawyers have a supreme court whose decision is their authority for interpreting the law. Infallibility is not claimed for their rulings always, for this same court has been known to reverse itself; yet in the main it is right and just and errors are the exception.

The therapeutists should likewise have an authoritative body possessed of every known means for determining the therapeutic action of drugs, free from every selfish interest, political or commercial, and from the bias of theorists, and not paid by some firm or individual to report the action of remedies placed in their hands, to

be put on the market under a trademark like any other commodity.

What an inestimable boon would such a body confer on the medical world if it could send out remedies for disease whose therapeutic qualities were definitely known and about which there could be no cavil, and if at the same time it could eliminate from text-books mention of all remedies which did not possess distinct therapeutic power.

Look at the things which are being accomplished by the government, state and national, in the biologic boards of research in determining the cause and cure of the diseases of plants and animals. The findings of such a body make the therapeutic law for application to all animals alike, whether their owners believe in pathology and rational therapeutics founded thereon, or follow the elusive delusions of christian science, or have no beliefs at all.

I would hail the day when the government should announce itself ready to establish such commissions for research into the etiology and cure of human diseases. Witness the one glorious result achieved by the immortal commission sent to Cuba for the investigation of yellow fever after the war with Spain. It has done nothing greater since the nation was born.

Finally I must conclude that the status of therapeutics to-day, considered as an organized system of practice, has lost its prestige under the blighting curse of commercialism, aided and abetted by the very men who are or should be its natural defenders.

I have presented some of my views on this very important subject, hoping to have the opinion of this society as to their worth or worthlessness. After all is said and done, research that does not find something of value for the cure of human ills is no better than a fruitless tree, an encumberer of the earth, and should be cut down.

In an address delivered before the graduating class of the medical department of the St. Louis University on May 8, 1905, Dr. John M. Dodson, dean of the medical department of the University of Chicago, said: "No doctor should prescribe any remedy whose formula is not known." Let this fact sink deep into our minds and make us resolve anew, each and every one of us, to do his utmost to drive the noisy commercialist out of our midst and to allow the present highways of trade to return again to the serene and thoughtful avenues of scientific pursuits. Then will rational therapeutics take its proper status and medical men everywhere be clothed with becoming dignity.

Test for Bile Pigments.—A. Raphael (*St. Petersburg, med. Wochenschr.*, No. 14), describes a method of testing for bile pigments in the urine which has been very satisfactory in his experience. He uses the well-known diazo reaction—first, sulfanilic acid (5.0), muriatic acid (50.0), distilled water (100.), and, second, sodium nitrate (.5) and distilled water (100.0). For the first test he puts 2 or 3 drops of the soda solution with about 5 cubic c.c. of the other and adds 5 c.c. of the urine to be examined. The presence of bile pigments will show itself, first, in an anesthetic color, passing in a short time to a cherry red. The intensity of the color increases in icterics during the first 24 hours. If the urine is very diluted, the red color is still visible against a white background. A second test is given as follows: To 2 or 3 drops of the soda solution added to the urine the sulfanilic acid is then added, and the fluid, according to the quantity of bile pigments present, takes on a more or less intense yellowish-green color, passing in the 24 hours to the above-described cherry red.

SPIROCHETE OBERMEIERI.*

F. G. NOVY, M.D., AND R. E. KNAPP, B.S.

ANN ARBOR, MICH.

PRELIMINARY NOTE.

The spirochete studied was obtained through the kindness of Dr. Norris of Bellevue Hospital, New York, who secured it from a case of relapsing fever by inoculating the blood into monkeys and white rats. The organism has been kept alive by successive passage through white rats for over two months. As a result of intraperitoneal injection the parasites appear in the blood in thirty-six to forty-eight hours after inoculation, disappear within the next twenty-four hours and do not reappear. The rats are then immune to subsequent inoculation. The disappearance of the spirochetes was shown to be due to the formation of anti-bodies. Spirochetal blood, when kept *in vitro*, retains its virulence for more than fifteen days.

The blood of rats which have been given repeated injections of spirochetal blood exerts a most marked preventive and curative action. When injections of such blood are made, before inoculation with spirochetes, the latter fail to appear. Similarly, when simultaneous injections of immune and spirochetal blood are made, no infection results. Even when the immune blood is injected ten, twenty-four and thirty-eight hours after inoculation with spirochetes, that is to say, at any time before the spirochetes actually should appear in the blood, they will fail to appear, whereas in the controls they become numerous.

The curative action of the immune blood is equally pronounced. In rats which have from 5 to 10 spirochetes per field of the one-twelfth inch objective, an injection of 2 c.c. of immune blood is followed *within one hour* by a total disappearance of the spirochetes from the circulation. After this, the parasites do not reappear, while in the controls they persist for twenty-four hours. This remarkable action of immune blood in the case of the white rat will form without doubt the basis of curative and preventive treatment in relapsing fever and in tick fever of Africa. It is the intention of the authors to work out the practical application of the principle discovered.

Spirochetal blood, which has been diluted with ten parts of salt-citrate solution, when filtered through a Berkefeld filter, under a pressure of 50 pounds, yields a filtrate which, when injected into white rats, produces typical spirochetal infection. This result was obtained in seven out of ten experiments. The spirochetes, as in the case of cultures of *Trypanosoma lewisi*, are filterable through a Berkefeld filter. Attention is called to the importance of this fact in its bearing on the so-called ultramicroscopic organisms.

All attempts thus far to cultivate the spirochete on blood agar have failed, but this subject will be followed further. The spirochetes multiply by transverse division and show other characteristics which belong to bacteria, notably, their behavior with reference to distilled water. When rat blood, which is rich in spirochetes, is placed in a thin collodion sac and dialyzed in running distilled water, the organisms do not undergo any change in form even after twenty-four hours. During the first five or six hours their motility is unimpaired, but after that they become more and more sluggish and finally come to rest. Even after a dialysis of eleven to twenty-four hours

such blood is infective. Under similar conditions the rat and nagana trypanosomes rapidly plasmolyze, within an hour or two, and become hardly recognizable. At the same time they lose their infectiveness.

This behavior of the spirochetes in distilled water, that is, absence of marked plasmolysis, corresponds to that of bacteria under like conditions. This test may, perhaps, serve as a more or less general means of differentiating between bacteria and protozoa. The transverse division of spirochetes, the absence of definite structure, such as the presence of well-marked nucleus and lepharoplast, and the absence of plasmolysis would indicate that the *Spirochete obermeieri* belongs to the group of bacteria.

On the other hand, the transmission of spirochetal diseases by insects, the persistence of the organisms in such insect hosts for months, and the infection of their eggs are the main facts known at present which point to a possible protozoal nature of the parasites. The persistence of the spirochetes of tick fever in the blood of rats for three to eight days, as shown by Dutton and Todd, would indicate that their organism, though closely related, is nevertheless different from that studied by us. It goes to show that the tick fever of Africa and the relapsing fever of Europe are due to different species of spirochetes.

INDICATIONS FOR STRYCHNIN AND NITROGLYCERIN IN CIRCULATORY DISORDERS.

ORVILLE HARRY BROWN, Ph.D., M.D.

Assistant Professor of Pharmacology, St. Louis University,

ST. LOUIS.

The pharmacologic action of nitroglycerin is erroneously conceived by some physicians. I have heard practitioners remark that "even the use of nitroglycerin and strychnin is ineffectual in causing a weakening circulation to recover." To understand the therapeutic indications for these two drugs in circulatory symptoms, a thorough knowledge of a portion of the physiology of the circulation is absolutely necessary.

The heart is a muscular organ which pumps the blood into the aorta at a rate which normally maintains the blood pressure constant, within certain narrow limits. The control of the heart's rate is automatic. The vagus and sympathetic nerves carry impulses to the heart; the former is the inhibitory nerve and the latter the accelerator. A small nerve running in the same sheath as the vagus, called the depressor, is the sensory nerve to the heart. The small blood vessels, the arterioles, have their caliber controlled by the vasomotor nerves. The centers of these four sets of nerves functionally must be intimately associated in the central nervous system. A rise of blood pressure, due to a constriction of the arterioles, or to an increased amount of blood, normally causes a slowing of the heart's rate. A fall of blood pressure due to causes, the reverse of those just mentioned, brings about an increase of the cardiac rhythm. Both changes in the rate of the heart's action are attempts, through the reflex nervous system, to maintain the blood pressure at the usual height. Any slight alteration in the caliber of the arterioles, or in the amount of fluid, or in the rate of the heart, is readily compensated for by the necessary change in one or both of the others. For example, a loss of a small amount of blood may not cause a fall of blood pressure, for the reason that the arterioles will contract, or the heart will increase slightly in either rate

*From the Hygiene Laboratory, University of Michigan.

or depth of beat. A gradual introduction of an isotonic sodium chlorid solution into the blood vessels produces no change in the height of the blood pressure. The compensation is by a dilatation of the arterioles or by a slowing of the cardiac rhythm.

It is due to the tension under which the blood is held in the aorta that the circulation through the periphery is accomplished. Indeed, the heart's function, strictly speaking, is to maintain the requisite pressure in the aorta; on this account the intimately connected system of nerves is necessary. The arteries which conduct the blood to the brain are fed from the aorta, and it is hardly necessary to state that anemia of the brain will result from a sufficiently low blood pressure; and the same is true of any other organ.

Since the heart is an organ which is continually working, it is necessary that there be no cessation of its supply of nourishment, or of the elimination of its waste. The arteries conducting the blood to the heart are branches from the aorta, and therefore the amount of blood passing through the coronary circulation depends directly on the tension of the blood in the aorta. A rise of blood pressure by some cause other than an alteration in the heart's rate, causes a slower heart rhythm in an attempt to compensate; but if compensation is not complete, more blood passes through the heart, and the resulting better nourishment and better elimination causes a stronger cardiac beat. A fall of arterial tension, as a result of changes in the amount of blood or in the size of the arterioles, causes, in an attempt to compensate, a more rapid rate of the heart's rhythm; but if compensation is not complete, there is a proportionate decrease in the amount of blood passing through the coronary vessels, and a poorer nourishment of the heart muscle, and decreased elimination of its waste, and consequently a less efficient systole.

Strychnin stimulates the vasomotor center. This results in a constriction of the arterioles and in a consequent rise of blood pressure, and therefore a better coronary circulation; this produces the improved systolic contraction described above. In some exceptional cases, strychnin has a stimulating effect on the vagus centers, thus bringing in the inhibitory effect of the nerve and slowing the cardiac rhythm. This may counteract the effect of the constriction of the arterioles to such an extent that there results no rise in arterial tension.

Nitroglycerin, which chemically is a trinitrate of glycerin, is decomposed in the body into nitrates and nitrites. The small amount of nitrates formed has little or no action in the body. The pharmacologic action of nitroglycerin is due, therefore, to the nitrites. The decomposition taking place gradually, there are no such sudden marked effects as in the administration of a pure nitrite. For the same reason, the effects are more prolonged from the administration of nitroglycerin than from administration of a nitrite. The nitroglycerin or a nitrite produces a dilatation of the arterioles of the body, and consequently a fall in the arterial tension, and there results a more rapid and a less efficient systole.

The therapeutic indications for either of these two drugs are perfectly clear: Strychnin is indicated when there is a low blood pressure, a rapid heart and a bounding and easily compressible pulse; nitroglycerin is indicated when the arterial tension is high, the heart rate slow, the pulse full and tense, and the wave very slight. In case of degenerative changes in the musculature of the heart the signs might be slightly different from the above.

The virtue of nitroglycerin in rendering aid to the heart depends on its reducing the resistance against which the systole works. For this reason it has incorrectly been said to be a cardiac tonic or stimulant.

Strychnin and nitroglycerin are directly opposed to each other in their effects on the circulation; and hence when one is indicated for its therapeutic effects on the circulation, the other is contraindicated. The former is indicated in cases of reduced and the latter in cases of increased arterial tension.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN. CHAPTER III.

ANALGESICS AND SOPORIFICS.

Analgesics and soporifics are among the most important articles in the materia medica, and at the same time, owing to their abuse, the most harmful.

The Common Need for Analgesics.

Pain, accompanied by sleeplessness, occurs in a great variety of conditions, often with an intensity or persistency that imperatively demands alleviation. When such a condition requires medicines for a long time there is danger that the patient will learn the name of the remedy employed and continue its use long after the actual necessity for it has passed. Certainly no other class of remedies requires more pain-taking care on the part of the physician, not only in the choice of the particular agent to be used, but also in the regulation of the dose.

Individual Treatment Imperative.

The way to secure the best results in the treatment of such conditions is by acquiring an intimate knowledge of the various remedies in this class and by learning how to use them singly or in combination as may be required.

In a given case a combination of chloral hydrate and potassium bromid may be necessary, while in another the latter alone may suffice. The more dangerous chloral hydrate should never be used when the less harmful bromid will serve the purpose.¹

If we find that scarcely any two successive patients demand exactly the same prescription consisting of but two ingredients, how very much less is the probability of finding any considerable number each requiring a "shotgun" prescription of five or six substances of widely different action, agreeing only in the one property of producing unconsciousness.

It should be obvious that the conscientious use of analgesics and soporifics demands the thoughtful selection of the remedy with the careful computation of the dose according to the necessities of the individual case—a condition manifestly impossible when one relies on complex, ready-made mixtures, with doses and indications suggested by an interested layman—the manufacturer. The greater the number of individuals who acquire such harmful habits the greater are the profits of the nostrum maker.

It is well known that the habitual use of opium, chloral hydrate, the bromids and other narcotics is widespread, but

1. Should the physician desire to use a compound mixture of chloral hydrate and potassium bromid of the bromidia type he would do well to have compounded the "Mixture of Chlorals and Potassi Bromidi Composita" of the National Formulary, as follows:

R. Chlorali hydratis	
Potassii bromidi, aa.....	54 gr. xv
Ext. cannab. Ind.	5
Ext. hyoscyami, aa.....	gr. 50
Aque q. s. ad.....	5vi 25

The chloral hydrate and the potassium bromid are dissolved in a little water and the extracts are then dissolved in the solution of the salts mixed with some powdered pumice stone, and the mixture filtered.

Each teaspoonful will contain approximately 1 gm. (15 grains) each of chloral hydrate and potassium bromid; 0.005 gm. (1/40 gr.) each of extract of Indian cannabls and extract of hyoscyamus, etc. The mixture should be used with caution, and it will usually be found advantageous to omit the extract of Indian cannabls.

there are few who appreciate the full extent of these practices, or in how far physicians are responsible because of the careless use of these agents, either in simple form or as an ingredient of some nostrum.

For more convenient consideration we shall divide these remedies into the opium, atropin, acetanilid, chloral hydrate and bromid groups, the first three being more properly analgesics and the last two soporifics, though no absolute distinction can be drawn between them.

The widespread use of opium and morphin for local action—injections and lotions—is based on an erroneous idea. Opium contains gum which is a demulcent, a rather expensive one, however, while its active principle, morphin, must be absorbed before it can produce its effects, which are constitutional, not local.

Official Preparations of Opium.

The importance of opium and morphin are such that their actions and uses should be carefully studied in standard works of the day, and we shall pass to the minor members of the group after enumerating the official preparations.

The danger that the patient will form the truly terrible opium habit from even a short use of this drug or of any of its derivatives should always be borne in mind, and when it is necessary to use them they should be masked. Hypodermics in pain have come to be almost synonymous with morphin in the minds of the laity. This idea should be uprooted both by the use of the method for many other substances and by avoiding it as much as possible with morphin. The odor and the taste of opium and of the tincture, unfortunately, are well known and they should be disguised if possible.

To disguise the identity of opium and its preparations it is customary with some practitioners to employ the old designation *thebaica* for opium; *tr. thebaica* for *tr. opii*. The use of the deodorized preparations of opium is also to be recommended for this same purpose.

The official titles, properly coming under the heading opium, are not only numerous, but varied and important. Opium and Opium Granulatum are never used directly in the practice of medicine, but *Opii Pulvis* and *Opium Deodoratum* are frequently prescribed.

OPII PULVIS.—U. S.—When assayed, by the process given in the Pharmacopeia, this should yield not less than 12 per cent. nor more than 12.5 per cent. of crystallized morphin. This requirement is somewhat higher than the provision adopted for the International Standard, which limits the morphin contents of powdered opium to 10 per cent.

Average dose: U. S. P. powdered opium is 0.050 (50 mg. or 1 grain).

OPIIUM DEODORATUM.—U. S.—This is powdered opium which has been treated with purified petroleum benzin to remove the caoutchouc, wax, oil and the odorous substances that are present; the alkaloidal strength and the dose of deodorized opium are the same as for the official powdered opium.

EXTRACTUM OPII.—U. S.—Assayed to contain 20 per cent. of morphin, this preparation is now little used, except in suppositories and the official emplastrum opii.

Average dose: 0.030 gm. (30 mg. or $\frac{1}{2}$ grain).

PILULE OPII.—U. S.—This is composed of opium, 0.065 (1 grain), and soap, 0.020 (1/3 grain). These pills constitute a very ancient form of administering opium.

Liquid Preparations of Opium.

There are five liquid preparations, the least useful of which is mentioned first:

VINUM OPII.—U. S.—Containing 10 per cent. of opium in fortified white wine, aromatized with 1 per cent., each, of cinnamon and cloves, it resembles the well known "Laudanum of Sydenham."

Average dose: 0.5 c.c. (8 minims).

ACETUM OPII.—U. S.—Vinegar of opium, formerly known as black drop, Lancaster drops or Quaker drops, has long been known and extensively used. It contains 10 per cent. of opium

and 3 per cent. of nutmeg in diluted acetic acid, sweetened with sugar.

Average dose: 0.5 c.c. (8 minims).

TINCTURA OPII.—U. S.—The Tincture of Opium is the well-known and widely used Laudanum, and consists of 10 per cent. of opium in diluted alcohol.

Average dose: 0.5 c.c. (8 minims).

TINCTURA OPII CAMPHORATA.—U. S.—This, also known as paregoric or paregoric elixir, is the only one of the compound preparations of opium now official. It is so well known as a mild anodyne and sedative that further notice is not necessary.

Average dose: 8 c.c. (2 fluidrachms). This amount contains about 0.03 gm. ($\frac{1}{2}$ grain), each, of powdered opium, benzoic acid, camphor and oil of anise.

The Deodorized Tincture.

TINCTURA OPII DEODORATA.—U. S.—Deodorized tincture of opium is practically a 10 per cent. aqueous, extract of opium that has been treated with purified petroleum benzin to remove the odorous and other objectionable constituents, and subsequently preserved by the addition of 20 per cent. of alcohol. This, like the simple tincture of opium, is directed to yield, on assay, not less than 1.2 per cent. nor more than 1.25 per cent. of morphin in crystals. The average dose is 0.5 c.c. (8 minims). While there has been some controversy as to who originated this particular preparation, there has never been any difference of opinion as to its possibilities and uses. From the sedative elixirs of nearly a century ago to the Scotch oats essence of the present day there have been many attempts to exploit deodorized or masked opium preparations, as harmless vegetable compounds. Another class of preparations, like "McMunn's Elixir of Opium," has been exploited as embodying some wonderful discovery in the treatment of opium.³ The official deodorized tincture is in every way distinctly superior to all of these nostrums, because, as noted under deodorized opium, it has the advantage of economy, efficiency and reliability.

Other Preparations of Opium.

There are but three other galenic preparations of opium official in the present Pharmacopeia.

TINCTURA IPECACUANILÆ ET OPII.—U. S.—Liquid Dover's powder. This is of practically the same strength as the well-known powder of ipecac and opium.

Average dose: 0.5 c.c. (8 minims).

PULVIS IPECACUANILÆ ET OPII.—U. S.—has been noticed under ipecac (see Chapter II). It contains 10 per cent., each, of ipecac and of powdered opium.

Average dose: 0.500 gm. (7½ grains).

TROCHISCI GLYCRRHIZÆ ET OPII.—U. S.—This has been previously noticed.

Morphin and Codein.

The alkaloids, Morphin and Codein, are of nearly as much interest as opium.

Morphin was discovered by Serturner, a German apothecary, in 1805, and was used in medicine as early as 1820. There are four official preparations:

MORPHINÆ.—U. S.—This alkaloid, obtained from opium, occurs as colorless or white shining rhombic prisms or as fine needles, or as a crystalline powder. It is odorless and has a bitter taste.

Average dose: 0.010 gm. (1/5 grain).

MORPHINÆ ACETAS.—U. S.—This salt of morphin should be kept in well-stoppered, dark amber-colored bottles, and a minute quantity of free acetic acid should be present to prevent decomposition.

Average dose: 0.015 gm. ($\frac{1}{4}$ grain).

MORPHINÆ HYDROCHLORIDUM.—U. S.—Like the acetate, this should be kept in well-stoppered dark bottles.

Average dose: 0.015 gm. ($\frac{1}{4}$ grain).

MORPHINÆ SULPHAS.—U. S.—Like the other morphin salts, this should be kept in well-stoppered dark bottles.

Average dose: 0.015 gm. (1/4 grain).

3. This preparation is superior to the widely used proprietary preparation of opium "Scaphin," over which it has the advantage of economy, activity and even general reliability since the accompanying directions for assay are not alone accurate, but are readily followed by one engaged in chemical assay work.

Sulphate of morphin is much the most frequently used in this country, while the hydrochlorid is generally given the preference in Europe. The acetate is the most readily soluble in water, but is quite unstable, losing acetic acid on exposure to the air, and, as the alkaloid morphin requires 3,330 parts of water for solution at ordinary temperatures, considerable care should be exercised in the use of old, and possibly decomposed, samples of morphin acetate.

While the new Pharmacopeia gives 0.015 gm. ($\frac{1}{4}$ grain) as the average dose of the salts of morphin we believe that this is too high as the "average" dose.

Cocain and two of its salts are official: Codeina, Codeinae Phosphas, Codeinae Sulphas.

Cocain, in addition to being obtained from opium, is also prepared from morphin by methylation. It was discovered by a French chemist, E. Robiquet, in 1832, but was not generally used in the practice of medicine until many years later. It was admitted into the U. S. Pharmacopeia in 1880; the phosphate and the sulphate are now official for the first time. The sulphate is the form most frequently employed in this country, though it appears to be but little known abroad, where the phosphate is mainly used. The phosphate was considered under the subject of Expectorants. Cocain has been considered a somewhat uncertain drug, owing to its frequent contamination with morphin, but the Pharmacopeia provides a test for its purity, and particularly for detecting the presence of the more poisonous alkaloid.

The phosphate, being readily soluble in 2.5 parts of water, is particularly well suited for hypodermic use; or it may be prescribed alone in syrup or combined with chloral hydrate or the bromids; in the latter case the mixture should be directed to be shaken before using.

The average dose of cocain or of any of its salts is 0.03 gm. (30 mg. or $\frac{1}{2}$ grain).

Apomorphin Free from Habituation.

APOMORPHINE HYDROCHLORIDUM.—U. S.—which was also mentioned under "Expectorants," Chapter 2, has been recently brought to notice as a hypnotic, in doses of 0.002 (1/30 grain). It is said to have the great advantage of not producing a drug habit.

Heroin and dinion are proprietary articles of the morphin group possessing some advantages, but they are not free from danger. The heroin habit is beginning to be common and should be carefully guarded against.

Cannabis Indica Unimporant.

CANNABIS INDICA.—U. S. AND BR. INDIAN CANNABIS is a well-known member of the opium group. It occurs in dark-green or brownish compressed masses, having an agreeable narcotic odor and characteristic taste.

It appears to have been used by the Hindoos from very early time. It was also known to the Egyptians and to Dioscorides, but it was not introduced into England until about 1835.

Average dose: 0.05 gm. (1 grain), but rarely used in substance.

EXTRACTUM CANNABIS INDICÆ.—U. S.—is an alcoholic extract reduced to a pilular consistence.

Average dose: 0.01 gm. ($\frac{1}{5}$ grain).

FLUID EXTRACTUM CANNABIS INDICÆ.—U. S.—Dose, 0.01 cc. (1 minim).

TINCTURA CANNABIS INDICÆ.—U. S.—represents 10 per cent. of the drug extracted with alcohol. Average dose, —0.5 cc. (10 minims).

At one time cannabis indica was supposed to have great virtues as an antispasmodic, analgesic and narcotic, and it was highly recommended by a few physicians as a vasomotor stimulant, uterine stimulant, etc. It is now but little used and there seem to be few conditions in which one of the preparations of opium could not, advantageously, be used in its stead.

4. It may be worth while to notice the importance attached to the extract of cannabis indica by the makers of bromidia, who claim that their preparation is the only hypnotic that has stood the test in every country for thirty years. Since all the other constituents are very commonly used, one must infer that they consider the "genioine imported extract of cannabis indica" of exceptional value. Bromidia. It is claimed by the manufacturer, contains 15 grains each of chloral hydrate and potassium bromid, and 1/8 grain each of genuine imported extract of cannabis indica and extract of hyoscy-

Other Members of the Opium Group.

Two other members of the opium group are Sanguinaria, which we have had occasion to mention elsewhere, and the tocolly-acting

LACTUCARIUM.—U. S.

Average dose: 1 gm. (15 grains).

TINCTURA LACTUCARIUM.—U. S.—is a 50 per cent. solution of lactucarium in diluted alcohol.

Average dose: 2 cc. (30 minims).

SYMPLEPS LACTUCARIUM.—U. S.—is much more commonly employed, its popularity being largely due to a nostrum.

Average dose: 8 cc. (2 fluid drams).

The Atropin Group.

The atropin group includes the crude drugs yielding the mydriatic alkaloids, such as atropin, hyoscyamin and hyoscin, or scopolamin, all of the latter being closely related chemically.

The actions of atropin and its congeners are so important and so complex that it is entirely beyond the scope of the present article to attempt anything like a complete description of them. The reader can not avail himself of this potent and important class of agents without a careful study of their pharmacologic and therapeutic actions. We shall, therefore, call attention to a few of their more important applications and contraindications without entering deeply into the reasons.

Atropin is useful as an analgesic mainly when the pain is of spasmodic origin and when the application may be made directly to the nerve ends of the affected tissues. In the pains of lead colic this may be accomplished by the internal use of one of the preparations of belladonna, preferably a pill of the extract coated with salol or keratin.

The most prominent action of atropin is seen in the dilation of the pupil, but the more rapidly acting and less enduring homatropin hydrochlorid is usually preferred for this purpose, if the object is merely to examine the eye—atropin, if it is desired to paralyze accommodation for some time, as in inflammatory conditions.

While the mydriatic effect is so similar with the different members of this group, it must be remembered that they have very dissimilar actions on the brain.

Use as Anesthetics.

The constant search for less dangerous anesthetics than ether and chloroform brings many substances into notice. Morphin and scopolamin have found an ardent champion in Korff, who has used them for several years. He employs up to 0.035 gm. ($\frac{1}{2}$ grain) of morphin and 0.0013 gm. (1/45 grain) of scopolamin. Unconsciousness does not occur and he claims absolute quiet must be maintained, while he stops operating long enough for pain to subside. He advises drops of chloroform or ether when necessary. The tongue must not be permitted to fall back into the throat. Its application in surgery must obviously be very limited. A discussion of a number of fatalities attending the use of morphin and scopolamin for general anesthesia will be found in *La Semaine Medicale*, Nov. 8, 1905, p. 529.

Scopola

The crude drugs and their preparations belonging to this class are so numerous and so well known that it is hardly necessary to enumerate them. Besides Belladonna Root and Leaves, Hyoscyamus and Stramonium Leaves, a member now official for the first time, is Scopola.

SCOPOLA.—U. S.—The dried rhizome of *Scopola carniolica* (Jacquin) (Fam. Solanaceæ), yielding, when assayed as directed in the Pharmacopeia, not less than 0.5 per cent. of its alkaloids, has little odor and a sweetish, afterward bitterish, acrid taste. Though described by Dr. Scopoli in 1771, it attracted but little attention from the medical profession until it was used in manufacturing "belladonna" plasters.

Average dose: 0.4 gm. ($\frac{3}{4}$ grain).

mus, to the teaspoonful. Thus a single repetition of the dose—one teaspoonful might prove fatal, since 30 grains of chloral hydrate have caused death; but the manufacturers advise *hourly* doses so long as may be necessary to induce sleep. The extravagant claims made by the manufacturers of this nostrum have induced many physicians to use it in preference to prescribing the several official constituents according to individual needs, and to day it is offered direct to the public at cut rate prices.

CHLORALHYDRATE SCOPORINUM, U. S.

Average dose: 0.05 c.c. (1 minim).

SCOPORAMINE HYDROBROMIDUM, U. S., is chemically identical with Hyoscine Hydrobromidum, U. S.

This has been used in the treatment of nervous excitement, particularly of the insane. It often induces quiet sleep at night—not usually in the day—and may also lessen sexual excitement. Atropin, on the other hand, has been used to stimulate the brain in cases of depression.

Average dose: 0.0005 gm. (0.5 mg., 1/125 grain).

Hyoscin is of Little Use as an Analgesic or Soporific.

HYOSCYAMINE HYDROBROMIDUM, U. S., and

HYOSCYAMINE SULPHAS, U. S. These are used very much as Hyoscin.

Average dose: 0.0005 gm. (0.5 mg., 1/125 grain).

None of the mydriatic alkaloids should be used as soporifics except in case of urgent need, as the benefits may be more than counterbalanced by the disadvantages. Hyoscin and hyoscyamine are of little use directly in relieving pain; hence, they can hardly be considered as analgesics.

Any of these alkaloids may be given alone as tablet triturates or as compressed tablets, hypodermically or alone in aqueous solution.

R. Tinctura belladonnae fl.

Tincture lobellae, of each 5℥ 10℥

Spiritus ætheris nitrosi, q. s. ad 5℥ 100℥

of this a teaspoonful is given every hour or two until relief is obtained.

The bromids of ammonium, sodium or potassium may be used with the prescription given, but in that case adjuvant or aromatic elixir should be substituted for the spirit of nitrous ether, and, as in every case when bromids or iodids are combined with alkaloids, the mixture is directed to be shaken.

The extracts of the crude drugs are much to be preferred to the alkaloids as additions to purgatives, since the latter would be largely absorbed from the stomach, whereas the local action on the intestine is desired.

(To be continued.)

Clinical Notes

AUTOMOBILE FRACTURE OF THE LOWER RADIAL EPIPHYSIS IN A SEVENTEEN-YEAR-OLD BOY.

FREDERIC WADE HITCHINGS, S.B., M.D.
CLEVELAND.

The following case is of interest on account of the method of occurrence of the fracture, its location and the absence of deformity which resulted. Inquiries of different surgeons indicate that automobile fractures in themselves are much more common than a search through the literature would indicate. Ghillini¹ has reported the only similar case that I have been able to find.

Patient.—H. P., a 17-year-old boy, was first seen on Sept. 30, 1905. He gave a history of having broken his nose when 2 years old and of breaking his ankle four years ago in a hockey game.

History of Injury. Three hours before I saw him he was trying to start the engine of a 10 horse-power automobile, when the crank snapped back. His right hand, which at no time left the crank handle, was quickly and violently forced upward, and he experienced severe momentary pain in his wrist, which was followed by a dull ache. He was positive that his hand grasped the handle firmly during this time.

Examination. This showed a moderate degree of swelling on the dorsal side of the carpus and lower radius and ulna. There was marked tenderness over the lower end of the radius and the voluntary motion of wrist and fingers was normal. There was no apparent deformity and crepitus was absent.

The drug of this group are so often used in asthma with benefit that we present the following as an example of the way they may be prescribed:

1. Zeph. L. Orphaned, *Chc.*, 1904, p. 759-61.

2. For an explanation of the use see Lind's article in the *Boston Med. and Surg. Jour.*, 1904, vol. 49, p. 481-3.

not obtained. Owing to the absence of deformity, an examination under ether was not made. The provisional diagnosis of separation of the lower radial epiphysis was made. Anterior and posterior splints were applied.

Fracture of lower radial epiphysis (tracing from x-ray plate by Stern). A, Line of fracture; B, line of epiphysis; C, radius; D, ulna.

The next day a Roentgen ray exposure showed that the parts were in normal position, but that there was a crack in the lower radial epiphysis. By that time the wrist was considerably broadened through swelling, and the point over the fracture was extremely tender. Routine treatment was followed.

A CASE OF CANCER OF THE PROSTATE (DIAGNOSED AFTER OPERATION).

FRANK S. BULKLEY, M.D.
AYER, MASS.

Patient.—W., aged 53, born in Ireland, foreman in tannery. **Family History.**—Both parents lived to an advanced age. One brother died at about the age of 50 of an indefinite trouble with urinary symptoms.

Personal History.—The patient had the commoner diseases of childhood, had had a right inguinal hernia for 15 years, but had never had any severe sickness. No venereal history. Habits always good; never drank, and smoked only in moderation.

Present Trouble.—About September, 1904, he began to notice some frequency of micturition. This continued, and during December, 1904, he consulted a physician, who examined the urine, told him it was normal, and prescribed a diluent. The trouble continued until August, 1905, when he consulted a second physician, with the same result. At this time he had to get up on an average of every hour during the night, the interval between urinations during the day approximating normal. There was practically no pain connected with the act. He never had noticed any bleeding.

Sept. 15, 1905, I saw the patient for the first time while he was suffering from an attack of retention, associated with the incontinence of retention. A silver prostatic catheter was passed with difficulty and one pint of clear urine drawn off. Catheterization at six-hour intervals was necessary for the next twenty-four hours, and then a soft instrument was tied in and the bladder drained for forty-eight hours. After drainage was discontinued the catheter was passed three times daily until the day of operation.

Physical Examination.—Well-developed man of apparently 50 to 55 years old. Rather stout. Color good. Pupils equal

and react to accommodation, and light knee jerks lively. Lungs negative. Heart not enlarged, sounds of good character and free from murmurs. Aortic second sound slightly accentuated. Pulse of rather high tension, vessels slightly thickened. Abdomen negative, except for right inguinal hernia. Prostate as felt per rectum moderately enlarged, firm, slightly tender and not nodular. Urethral length nine inches. Residual urine 280 c.c., sp. gr. 1012. No albumin or sugar, urea 1.70 per cent., no pus, blood or casts in sediment.

Operation.—Prostatectomy was advised, and the patient entered the Massachusetts General Hospital for operation. Suprapubic prostatectomy was performed Sept. 30, 1905, by Dr. James G. Mumford, the bladder being exposed by Noble's transverse incision. The enucleation of the prostate was extremely difficult, but the patient stood it well and was put to bed in good condition.

Microscopic Diagnosis.—Cancer apparently limited to prostate.

Later History.—For three weeks after operation the patient did well, when he had a gastric upset, and the amount of urine became diminished. This apparently uremic condition did not respond to treatment, and he died November 5. No autopsy was permitted.

In making the diagnosis of hypertrophy of the prostate in this case the possibility of its being a malignant enlargement was suggested by his age at onset and the short time elapsing before retention developed. Pain was practically absent, there was apparently complete absence of hemorrhage, and there was no weakness, much less cachexia. The latter facts were considered to be against a malignant enlargement.

The case is reported simply to put it on record because of its rarity.

SAFETY PIN SAFELY PASSED BY CHILD OF SIXTEEN MONTHS.

J. A. POSTLEWAIT, M.D.

TAKKIO, MO.

In THE JOURNAL of Nov. 25, 1905, Dr. L. W. Littig reported a case of a child eleven months old who swallowed a safety pin one and one-eighth inches in length and passing it in a few hours less than five days. No inconvenience was suffered and no treatment was given. Some time since I had an experience much the same with a child sixteen months old. In my case the safety pin swallowed was one and one-fourth inches long,

open, and three-fourths of an inch wide at the angle of opening. The safety pin was swallowed at noon on Saturday and on the following Thursday at 9 a. m. it was passed. The child did not suffer and no treatment was given.

New Instruments

AN IMPROVED PERIOSTEAL ELEVATOR AND SPATULA FOR SUBMUCOUS RESECTIONS.

CHARLES NELSON SPRATT, B.S., MD.

MINNEAPOLIS.

While not desiring to add to the large list of instruments devised for submucous nasal work, the instrument as shown in the accompanying illustration has proved of such assistance to me that I think it of sufficient value to merit publication. The instrument is 16.5 cm. long. The spatula measures 15x18 mm. and is a little over 1 10 mm. thick. The periosteal elevator is 5 mm. wide. The advantages of the double curve or "S" shape are as follows:

1. The curve of the instrument fits the hand and allows a firm grasp.

2. Although the force is applied in a straight direction, the hand is out of the line of vision, as with instruments having the "nasal angle."

3. The curve to the periosteal elevator is sufficient to cause the edge to stay in contact with the cartilage or bone.

4. The spatula end can be used as a retractor for the mucous flap or to hold it against the septum in inserting the packing. In either case the hand is out of the line of sight and the field of operation is unobstructed.

THE NEED OF A NEW SCALE FOR THE CLINICAL THERMOMETER.

L. D. PEEBLES, MD.

DENVER.

I desire to call the attention of the profession to the fact that an improvement in the means of quickly and accurately determining any deviation from the normal temperature is possible.

By the present method, when a temperature is 96.8 degrees it takes at least a little time to find that it is 1.6 degrees below normal. If it is 102.4 degrees it likewise requires more than a glance to see that there are four degrees of fever.

In the improvement that I suggest the exact amount above or below normal is at once seen, as I would have on the new scale the letter N to represent normal, which on the present scale is 98.4 degrees, and have it marked off in full degrees with fifths above and below.

Thus a temperature of 102.4 degrees on the present scale would be exactly four degrees above normal on the new scale and could be so recorded, while a temperature of 95.4 degrees on the present scale would be exactly three degrees below normal on the new scale.

As the clinical thermometer is only used for medical purposes, I think it full time that we should have one all to ourselves.

New Scale.

N	represents	98.4 degrees
1 degree	above represents	99.4 degrees
2 degrees	above represents	100.4 degrees
3 degrees	above represents	101.4 degrees
4 degrees	above represents	102.4 degrees
1 degree	below represents	97.4 degrees
2 degrees	below represents	96.4 degrees
3 degrees	below represents	95.4 degrees
4 degrees	below represents	94.4 degrees

Present Scale.

[EDITOR'S NOTE.—We agree with Dr. Peebles that his suggestion is a valuable one, but we should prefer to have the scale which he proposes added in another color to a thermometer which already had the present scale. Thus one could tell the actual temperature or the deviation from normal, as preferred. If Dr. Peebles' scale alone were on the thermometer a sum in addition would be required in order to secure the actual Fahrenheit temperature for record or for comparison with the other system. Of course, it will not be possible immediately to do away with the old system and a new thermometer should have the old scale on it for comparison.]

SATURDAY, JANUARY 13, 1906.

THE TRANSMUTATION OF SPECIES IN BACTERIOLOGY.

The doctrine of the transmutation of species, of the conversion of one kind of organism into another, has a ways had and doubtless will long continue to have a fascination for a certain class of minds. At one time some naturalists saw nothing improbable in the metamorphosis of barnacles into geese or even of the trunks of trees into large animals. As regards lesser forms of life the doctrine of heterogenesis was almost a universally accepted scientific belief. In the early days of bacteriology the notion of transformation among such exceedingly minute organisms as bacteria found, as was natural, many adherents, and the half-understood facts and but slightly trammelled fancies put forward by Beauchamp, Billroth, Naegeli and others left an indelible mark on the young science. In recent years the veteran Bastian has continued to advocate the spontaneous generation of micro-organisms out of non-living matter, and it was but yesterday that the "radiobac" was welcomed with easy credulity. DeVries' theory of mutation has seemed to some to afford support to the doctrine of transformation, although such an interpretation appears to us to be based on a misunderstanding of the nature and scope of mutations. On the whole, it is not surprising that instances of the change of one bacterial species into another should be brought confidently forward from time to time for confirmation. The view once held by a certain school of French bacteriologists regarding the transformation of *B. coli* into *B. typhosus* has, to be sure, been virtually abandoned, but belief in the fluctuating character of the species in the colon typhoid group is still active.

Recently the alleged transformation of *B. (fecalis) alcaligenes* into *B. typhosus* has been the theme of appreciative comment. Aitschuler observed that when cultures of *B. coli*, *B. paratyphosus* and *B. typhosus* were cultivated on a sterile human placenta the two former organisms remained unchanged, but after from four and one-half to six weeks the original culture of *B. typhosus* developed a yellow growth on potato, produced alkali in litmus and became inagglutinable by typhoid serum.

Conversely, under other conditions a culture of *B. alcaligenes* seemed to change into *B. typhosus*. These results of Aitschuler were apparently confirmed by Doeberl,¹ who concluded that "the culture of our labora-

tory, labeled '*B. f. alcaligenes* (Petruschky)', is so changed by passage through the bodies of three guinea-pigs that it is no longer to be distinguished by the ordinary methods—culture, agglutination—from a true typhoid bacillus." Berghaus,² however, assistant in the same laboratory, has now ruthlessly shown that the culture with which Doeberl worked was not a pure culture, but was a mixture of two kinds of bacteria. One of them was the true typhoid bacillus, the other *B. alcaligenes*. In brief, what happened in Doeberl's experiments was that as a result of animal passage *B. alcaligenes* went to the wall, while *B. typhosus* survived and was isolated in pure culture at the finish. Trommsdorff,³ assistant in the Munich laboratory, has also reached, independently, the same results as Berghaus; he concludes from a series of experiments that the typhoid bacillus and *B. alcaligenes* are "well differentiated species." This is not the first denouement of the sort in bacteriology, and the occurrence may well suggest to bacteriologists the importance of testing the purity of a culture by multiple plating or in other ways. The question naturally arises as to how far the perplexing results obtained by some investigators, for instance, those working with the pneumococcus-streptococcus group, can be attributed to cultures of doubtful purity.

SURGICAL ASPECTS OF FOOTBALL.

We have called attention several times to the number of deaths that take place every year from football, and have emphasized the fact that in the season just passed more than a score of fatalities were reported as having occurred. This, of course, is too large a number of fatal accidents for any mere sport. There must be something in it besides sport, an appeal to the brutal instincts of human nature, or some less worthy incitement even than this, to make young men continue to indulge in a game which is the cause of so many deaths. It has been said over and over again, however, in answer to any such arraignment of the game, that the fatal accidents take place only on minor college teams, where the men are not properly trained and hardened to stand the brunt of the necessary football severities. Serious injuries are said not to occur at the large universities. The very obvious retort would be that since the smaller colleges imitate the large universities, which are supposed to be the great centers of culture in this country, it is too bad that the example set must have such serious consequences.

As the conclusion of a recent careful medical study of the game and its attending injuries, there is, however, a much more direct and forceful answer that may be given to the objection. Dr. Edward H. Nichols and Dr. Homer B. Smith, who had the medical and surgical care of the football squad of Harvard during the past season, have given their observations and conclusions in

1. Hygiene Institute, Univ. of Berlin.

2. Hyg. Rundschau, 1905, 15, p. 761.

3. Münch. med. Wochsft., 1905, 52, p. 1667.

an article¹ on "The Physical Aspect of American Football." We may say at once that their conclusions are entirely against the game as judged from its medical standpoint. They say that the number, severity and permanence of the injuries which are received are very much greater than is generally credited or believed. They consider a large percentage of the injuries unavoidable, and state that constant medical supervision of the game is a necessity and not a luxury. At Harvard the constant attendance of two trained surgeons is required. Furthermore, they consider that the number of injuries is inherent in the game itself, and is not due especially to close competition in big games, since the proportion of injuries received in games and in practice is about the same.

Some of the details of the report on which these conclusions are based make a very interesting surgical catalogue. Of cuts that required stitches there were 12; of fractured ribs there were 5; of dislocations of the shoulder, 2; ruptured muscles, 6; dislocated semilunar cartilages, 10; broken noses, 7; fracture of the rim of the pelvis, 4; dislocation of the acromial end of the clavicle, 11; concussion of the brain 19; fracture of cervical vertebra, 1; and middle meningeal hemorrhage, 1. A young surgeon who desired the training of an active practice in rather serious surgical injuries of very varied nature evidently could not do better than to obtain the appointment as attending surgeon to a football squad. Now that war's opportunities are lacking for surgical practice, this chance should not be forgotten. As is very well said by the authors of the report, many of the joint injuries received are of such a character as to be likely to become progressively worse, and many of the injuries to the shoulder are certain to cause some disability in later years.

Perhaps the most serious feature of these accidents is the number of concussions of the brain reported. Only two games were played during the entire season in which a case of concussion of the brain did not occur. Frequently the fact that a man had received this serious head injury was noted by the surgeon from the side lines before it was recognized by the player. At times a man thus hurt continued automatically to go through the motions of playing until his mates noticed that he was mentally irresponsible. When a condition like this develops as the result of an injury, the central nervous system has received a very severe shaking up. There was a time when it was considered that convulsions and other untoward incidents in the conscious life of the individual were not likely to be followed by serious consequences. This is not the opinion at the present time, however. One of the questions always asked by nerve specialists with regard to nervous diseases developing later on in life, is whether or not the individual ever suffered from convulsions in childhood. A state of affairs in which the individual acts as an automaton after an

injury is not so different in character from a convulsive seizure. If the one is supposed to have serious consequences so may the other. At the present time no one is ready to say whether concussion of the brain may or may not have serious consequences in after life.

The whole report of the two surgeons in charge of the Harvard squad should be read by every prominent educator throughout the country, and it should be the duty of the members of the medical profession to see that it is called particularly to their attention. Surely, no one will consider after this calm exposure of the inside history of football injuries, even at a great university where no effort is spared to bring the men into the pink of condition, that football is to be considered a game without serious risks, no matter what the preparation, or that it is to be compared with any of the other sports in this matter of liability to serious injury. An attempt has been made to gloss over football's worst aspects by widely published suggestions that no game is entirely without the danger of death under accidental circumstances. In football, however, as the Harvard surgeons emphasize, the injuries are absolutely dependent on the present methods of playing the game itself, and are bound to occur. The fact that 145 injuries, for that is the total of the Harvard record, the least of which were cuts—twelve in number requiring stitches—occur in one season of play is of itself enough to stamp the game as something that must be greatly modified or abandoned if we are to be considered a civilized people, and if our universities are to be considered centers of influence for good. The additional conclusion in the report that the game as now played encourages weight too much at the expense of nervous energy to be really athletic, should be its death knell in its present form unless our university authorities fear unpopularity more than they dare to be right.

THE SPIROCHLETA PALLIDA.

As further reports concerning this protozoön appear it becomes more possible that Fritz Schaudinn and Erieh Hoffmann, the discoverers of the *Spirochæta pallida*, have found the micro-organism that causes syphilis. Schaudinn and Hoffmann have contented themselves, however, with merely stating that this parasite is found constantly in all syphilitic lesions of the secondary stage, and do not assert that it therefore produces the disease.

Since their first report last May, the *Spirochæta pallida* has been found in various syphilitic products by more than 100 observers, and the amount of literature that has appeared is proof of the interest aroused in the subject. As Koch had to face the assertion that the tubercle bacillus was merely a fat crystal, so Schaudinn and Hoffmann had to meet the argument that their spirochete did not differ from the common ones already known to bacteriologists, and that the micro-organisms had merely grown in the staining fluid as a culture medium after its accidental contamination. Their convincing description of their work, however, soon silenced

such trivial opposition, and since then confirmations of their findings, accompanied in many instances by microphotographs, have been pouring in.

The *Spirochæta pallida* is not a fission fungus, but is of animal nature, an animal micro-parasite or protozoön of the group *Flagellata*. In contrast to this, the well-known spirilla, which resemble it in form, are vegetable parasites. The form of the *Spirochæta pallida* is that of a very thin, corkscrew-like thread with regular, numerous spirals, deep and close together. The pallida is the smallest of the spirochetes. Its length varies from 1 micro-millimeters to 20 in exceptional cases. It is probable that such long specimens are produced by end-to-end apposition of several individuals. The thickness of the *Spirochæta pallida* varies from immeasurable slenderness to one-fourth of a micro-millimeter. At each end of the organism there is a slender, straight, hair-like flagellum, and some of the micro-parasites have two of these at one of the poles. The *Spirochæta pallida* is capable of various motions. One of these is of a screw nature, the animal rapidly rotating on its axis in one direction and then reversing the motion. There are also bending, sinuous and whip-like movements of the entire body. The motions persist even after six hours in physiologic salt solution. No cultures have been obtained so far from any type of spirochete.

The *Spirochæta pallida* is very difficult to stain and after staining appears much more faintly colored than the common varieties of spirochetes. The stain employed by Schaudinn and Hoffmann is Giemsa's eosin azure solution. H. Ploeger has also succeeded in staining it with a one-minute immersion of the slide in a 10 per cent. concentrated alcoholic solution of gentian violet with 2.5 per cent. of carbolic acid. The parasite may be seen with an oil immersion lens and magnifying power of 800 diameters.

In balanitis, serofulous abscesses, papillomata and the scrapings from carcinoma spirochetes have been found that resemble in appearance the *Spirochæta pallida*. These common forms, however, possess an undulating membrane, readily seen as a shadowy outline, and they are usually much coarser than the pallida. The spirals flatten when they are at rest, while those of the *Spirochæta pallida* are preformed and constant. Though exceptionally slender, forms of these common spirochetes may resemble the pallida; they are always mingled with the coarser specimens of the micro-organism, while the *Spirochæta pallida* exist in pure culture in syphilitic tissues. The *Spirochæta pallida* has been found in the deeper layers of primary lesions, in fluid extracted from syphilitic inguinal glands, in secondary papules, in the blood of the spleen at the time of the syphilitic rosola and in the spleen of a child who died of congenital syphilis. Nearly pure cultures have been found in the fluid from syphilitic pemphigus blisters. Metschnikoff mentioned an ape with syphilis and found the *Spirochæta pallida* in the primary lesion produced. The micro-parasite has never been demonstrated in the tertiary products of

syphilis. The *Spirochæta pallida* is difficult to see, so that practice is required before it can be readily found in specimens examined. Further research, perhaps extending over years, will be needed to establish it as the micro-parasite that causes syphilis or to disprove its claim to such distinction. Meanwhile, the number of those studying it is on the increase and interesting developments are to be expected.

THE APPENDICES EPIPLOICÆ AS A CAUSE OF ABDOMINAL DISEASE.

It would almost seem that the enormous number of abdominal operations which are now done each year would have made us acquainted with not only the most common but also the most uncommon intra-abdominal lesions. That this is not entirely the case is shown by the cropping up, from time to time, of conditions which are not mentioned in the ordinary textbooks and are often but barely noted in the literature. At first sight some of these conditions seem so unusual and bizarre that we are apt to regard them as mere medical curiosities, and to think of them as conditions which may be left to the consideration of the diagnostic hair-splitter, but which have no great interest for the practical physician. The history of many of these apparent medical rarities shows, however, that, once pointed out, they become more and more common, and the publication of a single case is often followed by a veritable avalanche of reports of a similar nature.

The lesions which may be produced by changes in the appendices epiploicæ have as yet received but little attention, and it is hardly realized that they are probably not so very uncommon. A year ago Rixford¹ called attention to the clinical aspects of inflammation of these bodies, and more recently Riedel² has reported the results which may follow their elongation and detachment. In case of inflammation the symptoms produced usually simulate those of a mild attack of appendicitis, but differ from the ordinary case in that the localizing symptoms are on the left instead of the right side. Very often there has been antecedent constipation over long periods, and attacks of left-sided pain and tenderness with nausea and perhaps vomiting may have recurred at intervals.

The conditions which may result from the elongation of the appendices are either the production of intestinal obstruction from the mechanical action of the bands so formed or the detachment of the free and often enlarged end of the involved appendix epiploicæ which is then present in the peritoneal cavity as a free body. More rarely an elongated appendix may become part of the contents of a hernial sac, become twisted and give rise to the symptoms of a strangulated hernia. In the cases in which intestinal obstruction is produced the symptoms are those usually associated with this condition, and it is, of course, impossible to make a diagnosis be-

1. California State Jour. of Med., ii, No. 10.

2. Münch. med. Wochsft., lli, No. 18.

fore operation. The free bodies in the peritoneum may give rise to symptoms suggesting gallstones, recurrent attacks of pain and sometimes slight jaundice, or appendicitis may be simulated. In some instances a fatal peritonitis has been produced.

The explanation of the production of such marked symptoms by such small and apparently innocuous masses of fat is difficult, and the symptoms do not correspond at all to what we should expect from our knowledge of the resistance of the peritoneum. In one instance Riedel was able to cultivate the colon bacillus from the interior of such a free, fatty body, which showed every evidence of having been in the peritoneal cavity for some time. It is, of course, possible that the bacteria entered from the intact intestine, a process which might be rendered more easy by association with false diverticula, which are not uncommon in connection with changes in the appendices epiploiceæ. Riedel's article in particular shows that these structures give rise to intra-abdominal conditions much more frequently than has hitherto been supposed, and we may expect that such cases will assume greater importance in the future.

RECIPROCITY BETWEEN NEW YORK AND NEW JERSEY.

In this issue¹ will be found the rules regulating reciprocity between New York and New Jersey. The examining and licensing boards of these states met last October and compared their methods of procedure as regards the licensing of physicians. After a full discussion they adopted the rules as published and recommended the amendment of the laws in one or both states, thus doing away with a number of minor differences now existing. This is a step in the right direction. Such adjustments should be made in the various states until there is a single standard regulating the practice of medicine in this country to displace the present chaotic conditions in which each state has a standard of its own.

MEDICAL STUDENT REPUTATIONS.

There have recently occurred among medical students class rushes and fights such as take place from time to time in literary colleges, and they are certainly a discredit to the alleged maturity and common sense of professional students. Such happenings are sometimes condoned in undergraduates of literary colleges on account of the immaturity of the participants; in any case no sensible person wishes to repress a proper youthful spirit of fun, but there should be a line drawn, beyond which no student dare go without summary action by college authorities. When one has attained the years which are supposed to be of discretion and suitable for the higher professional studies, and when one is a candidate for—or one might almost say member-elect of—an honorable profession it is time to have regard for reputation. The reputation of medical students is one of which every respectable medical man is ashamed, and those in charge of medical colleges are responsible for

it to a large extent. Every well-wisher of the profession will echo the sentiments of Dr. Roswell Park, who, because of the street fights by Buffalo professional students, wrote to the student fraternities urging them to remember that their members already bear some responsibilities as men and members-elect of various honorable professions.

A SUBSTITUTE FOR THE OYSTER.

The importance of the oyster as a food and as a factor in the etiology of typhoid fever render a possible substitute for it of medical interest. The abalone² is a giant snail, weighing from one to two pounds, living in practically unlimited quantities in the deep waters of the ocean, and easily gathered along the entire coast of central and lower California. The flesh is a nutritious and wholesome article of food, highly esteemed by the Chinese and Japanese, but as yet very little used in the United States outside of California. The drying process and the original canning method yield a tough product, but a process has recently been discovered by which these giant snails can be canned and made as delicate as the oyster. They are used in a similar way for food, but have the decided advantage over the oyster that when gathered the viscera can be detached from the muscular parts by the single stroke of a knife. The source being on less populated coasts, offers less danger of typhoid contamination than does that of the oyster and, further, we understand that there is no necessity for fattening the abalone in creeks, as is the case with the oyster. These points are in favor of the new mollusk and seem to give it large possibilities as a food product.

ALLEGED INFIDELITY OF PHYSICIANS.

A clergyman, officially high in his denomination, publishes some statements in a religious paper³ that are—to say the least—misrepresentations. He begins by saying that the majority of physicians are infidels in the proper sense of the word, and of medical students he says that "a more ribald, obscene and godless set of young men is not to be found." Later in their careers he practically charges them with habitually lying to their patients; and says that the deteriorating effects of this, with the influence of materialistic views, the habit of neglecting religious worship (which, he says, is general among them), and the constant association with suffering, sickness and death, make them calloused and hardened and non-religious if not actively irreligious. He claims to have been a medical student, and doubtless can speak for himself at that stage of his career, but this does not justify him for slandering the whole class at the present or at any other time. His knowledge of modern medicine is evidently not great, for he says that after 6,000 years of study of the human body the medical profession is unable to explain the use of its largest organ, the liver. His quotation of Sir William Gull, whom he represents as saying that he was correct in only 66 per cent. of all his diagnoses, is, without its context, unjust to that eminent practitioner, who must have made

1. Scientific American, Dec. 16, 1905.

2. Church Standard (Episcopal), Philadelphia, Dec. 23, 1905.

3. Department of "State Boards of Registration," page 142.

the remark with many qualifications and reservations, if he made it at all. The clergyman asks if this is so "what would be the proportion of correct diagnoses of the ordinary physician?" Certainly, for all practical purposes, much better than the above figures, even with the very "ordinary practitioner." The motive of the article seems to be a sort of clerical jealousy of the physician and the magnification of the healing value of the ministrations of the spiritual adviser. We regret to have to make a criticism of a clergyman, for we believe that he represents in these views very few of his colleagues. No honorable physician would wish to deprive his patients of any benefit he can obtain through the ministrations of religion and its representatives. Physicians are not non-religious as a class, however apparently irreligious some of them may be, and it is not at all becoming for a clergyman high in his church to exaggerate or to try to widen the breach that he imagines exists between his own and the medical profession.

SUTURE OF THE DIVIDED SPINAL CORD.

The extraordinary advances that have been made by modern surgery are nowhere better exemplified than in the treatment of certain disorders of the nervous system, especially those of traumatic origin. In numerous instances life has been saved by timely operation for the relief of pressure from fractured or depressed bone or for the control of hemorrhage from a lacerated cerebral blood vessel. Less frequently similar results have been obtained in the case of comparable lesions affecting the spinal cord. On the basis of the experience already gained there is good ground for hope of further brilliant accomplishment as a result of surgical endeavor in this direction. A case in which the spinal cord severed by a bullet has been successfully sutured has been placed on record by Drs. Francis T. Stewart and R. H. Harte, and a second case of similar nature has recently been reported by Dr. George Ryerson Fowler.¹ The patient was a clerk, 18 years old, who was shot in the back with a .38-caliber revolver, the bullet entering the body at a point one and one-quarter inches to the right of the median line on a level between the tenth and eleventh dorsal vertebrae. He suffered severely from shock and immediately exhibited paralysis of the lower extremities, with loss of sensibility up to the level of a line one inch above the crests of the ilia behind, and midway between the symphysis pubis and the umbilicus in front. There was loss of control of sphincters of bladder and bowel, without continuance of movement of the bowels; and muscular twitching in both legs and especially in the toes. Operation was decided on, and on removal of the laminae of the tenth, eleventh and twelfth dorsal vertebrae the cord was found divided, with the bullet lying transversely between the tenthitis and concealed from view by a large clot of blood. Bullet and clot were removed and the cord was united by means of three separate sutures of catgut sinuses. The further surgical work of these cases was uneventful and there was some sensation in the extremities, but the motor pulse and the loss of control of sphincters persisted. The two cases reported demonstrate the wisdom of prompt surgical

intervention, even in cases heretofore considered hopeless, and they further constitute evidence of at least a certain power of regeneration or at any rate of union on the part of the divided spinal cord.

RAILROAD CO-OPERATION IN PROPHYLAXIS.

It is a common rule among the railroads of this country that employes must not drink liquor while on duty, but it is not so common to find the railroads making provisions for their employes which shall lessen the desire to drink. A foreign exchange announces that the Prussian authorities, in enacting rules of this kind, have made arrangements to aid their employes by providing at accessible points good drinking water and boiling water for the making of coffee; and, further, at places where many men are gathered, cafés are to be installed where non-alcoholic drinks can be obtained at low prices. This is a very commendable work and is carried on to a limited extent in this country. As one means to this end, the branches of the Young Men's Christian Association are aided by the railroads as a means of keeping employes in good surroundings. These contributions are commonly charged to the head of betterment of equipment. The president of one of the largest lines in the country has publicly announced that of all the items under the head of "betterment" in the expenses of his road, the greatest returns are received from the subscription which his road makes to the maintenance of Young Men's Christian Association branches. The suggestion as to co-operation with employes in carrying out various rules as to conduct and habits will be of value to superintendents of hospitals and nurses' training schools, medical college deans and others. The keeping of rules of conduct may be favored by the conditions which surround those concerned and which too often are disregarded by the authorities who could better them.

UNWISE ATTEMPTS AT CLIMATIC TREATMENT OF TUBERCULOSIS.

The value of climatic treatment of tuberculosis may be largely or wholly destroyed by the absence of other details of treatment which are considered by many no less important. We recently called attention to the protest of New Mexico physicians against the migration to that state of consumptives without means of support. Unable to secure employment in a market already glutted with others like himself, the consumptive soon finds himself living in poor quarters, eating scanty and cheap food, worried by his future prospects and with very little possibility of improvement in health. Whatever climate can do for such a person is certainly effected in spite of immense odds. During the recent Tuberculosis Exhibition in New York City, the Committee on the Prevention of Tuberculosis of the Charity Organization Society sent a letter calling attention to these facts to the physicians of New York City. The profession of the whole country needs to be reminded again that the removal of a consumptive to another climate will defeat its own aims unless the sick one has means to pay his expenses or has secured in advance an arrangement for his support.

Medical News

ILLINOIS.

Chicago.

Personal. In honor of his seventieth anniversary, a dinner was recently given Dr. Isaac N. Danforth by the Therapeutic Club.

Cornerstone Laid.—The cornerstone of the new Englewood Union Hospital was laid with elaborate ceremony, December 3. H. C. Staver presided, and Dr. A. P. Foss placed the stone in position. The new building will cost about \$85,000, will be five stories in height, fireproof and equipped in accordance with the most advanced views.

Children's Hospital Society.—At the annual meeting of the Children's Hospital Society Dr. Frank Billings was re-elected president, and Dr. Frank S. Churchill was elected secretary. The president in his address announced that since the organization of the society beds in children's wards in various hospitals of Chicago had increased from 290 to 450. It was proposed to establish tent sanatoria in all the small parks for the children of working mothers, where specially prepared milk might be obtained. The most important work for the society just now is to arouse public interest in the proposed children's hospital for infectious diseases.

Physicians Notified.—Notices have been sent to 3,800 physicians of Chicago, by the Department of Health, calling attention to the new law which provides that every physician who attends any person having a contagious or epidemic disease, such as cholera, yellow fever, scarlet fever, diphtheria, typhus, typhoid fever, smallpox, varioloid, puerperal fever, membranous croup, measles or whooping cough, shall report cases within twenty-four hours, giving the name of the patient and a description of the disease. A fee of 10 cents is allowed for every report, and a penalty of from \$10 to \$200 may be imposed for failure to obey this law.

IOWA.

Endows Bed.—John Norton of Fort Creek, Neb., has given \$4,000 for the endowment of a bed in the Jennie Edmundson Memorial Hospital, Council Bluffs.

Objects to Publicity.—Woodbury County Medical Society, at its last meeting held in Sioux City, adopted resolutions that no member should allow his name to appear in the lay press in connection with any case or in any interview on medical subjects.

Personal.—Dr. Fred P. Bollinger, Council Bluffs, has left for the far East, via Japan. He hopes to reach Thibet. Dr. W. W. Nesmith, Waukon, has gone to Pensacola, Fla., for the winter. Dr. an Mrs. Charles C. Bradley, Manchester, have gone to Southern Pines, N. C., for the winter.

County Society Election.—The Medical Society of Chickasaw county met in New Hampton, December 4. The following officers were elected for the coming year: President, Dr. Edwin N. Johnston, Frederickshurg; vice-president, Dr. L. M. Taylor, Frederickshurg, and secretary, Dr. James F. Torpey, New Hampton.

MARYLAND.

Hospital Report. The Emergency Hospital, which is conducted under the auspices of the Frederick County Medical Society, in its second annual report, shows that 379 patients were treated, of whom 204 were surgical cases, with one death after operation, and a total of nine deaths in the hospital. There were 138 free and 122 part-pay patients. The Board of State Aid and Charities made no recommendation for legislative appropriations to this hospital, speaking of it as "somewhat limited in scope."

City Insane in State Hospitals. There are 40 more insane patients being cared for by the city now than a year ago. On January 1 there were 1,334 such patients, of whom 720 were in state hospitals, 219 in Mount Hope Retreat and 395 in Bayview (city almshouse). For each of these the city pays annually \$150 to the several hospitals; but it was reimbursed by partial payments to the extent of about \$12,000 during 1905. In their report the supervisors "hope that the policy adopted by the state in 1904 of taking over the care of all indigent insane patients will be vigorously carried out."

Baltimore.

Left Large Estate. The estate of the late Dr. George W. Wittenberger amounted to nearly \$250,000, of which \$50,000 was in real estate.

Births and Deaths. There were 201 deaths and 406 births reported for the week ended January 6. There were 35 deaths from pneumonia and 23 from consumption. Six new cases of smallpox were reported.

Refused Vaccination.—Eleven members of the crew of the British steamer *Jessie Burns*, from England (on which there was a case of smallpox on her arrival, December 31), refused to be vaccinated on board and were brought to the jail and there forced by the police to submit.

Hospital Opened. The Franklin Square Hospital, attached to the Maryland Medical College, was formally opened January 6. Among those who took part in the ceremonies were Bishop William Pare, Governor Edwin Warfield, Mayor Timonium, Dr. James Bosley, health commissioner, and State Senator J. Charles Linthicum. The improvements cost about \$50,000. The building, as remodeled, is 84 by 100 feet, and the capacity is about 100 patients. Dr. Joseph H. Branham is president of the board of directors.

Reception to Dr. Osler.—Dr. William Osler reached Baltimore from Canada, January 5, and took up his quarters at the Johns Hopkins Hospital as the guest of Dr. Hurd. A reception was tendered Dr. Osler on the evening of January 6, in the rotunda of the hospital, members of the faculty, the house physicians and medical students attending. January 23 he will deliver an address before the Maryland Association for the Relief and Prevention of Tuberculosis, at Annapolis, in advocacy of a state tuberculosis hospital.

Personal.—Dr. William H. Welch has been notified of his election as president of the American Association for the Advancement of Science at New Orleans, January 1.—Dr. Alfred Dohme sailed for Bremen, January 5.—Dr. Howard D. Lewis has been appointed health warden and vaccine physician of the Twenty-second Ward, to succeed Dr. Albert T. Chambers, resigned.—Drs. Robert T. Wilson, Hiram Woods and H. A. Bond have been elected members of the board of trustees of the Female House of Refuge, the latter being made secretary of the board.—C. A. Emerson, Jr., has been elected chemist and bacteriologist to the sewerage commission.

MASSACHUSETTS.

Cremations Increase.—The Massachusetts Cremation Society reports that the number of cremations during 1905 was 225, as compared with 211 the previous year. Among the cremated was the body of Dr. James R. Chadwick, who was president of the society.

Epileptic Hospital Report.—The Massachusetts Hospital for Epileptics reports that during the year 618 patients were cared for at an average weekly cost of \$4.56 per capita. Of the same patients 12 were discharged much improved, 10 improved, 13 not improved and 11 died. Of the insane, 1 was discharged recovered, 1 much improved, 5 improved, 2 not improved, and 13 died.

Tuberculosis Control.—The Boston Association for the Relief and Control of Tuberculosis reports that during the last year its visitors instructed in their homes 716 patients; a day camp at Parker Hill was maintained during the summer months, at which 128 patients were cared for, and largely through their efforts the tuberculosis exhibit in Horticultural Hall was made possible.

Recommends Inspection of School Children.—In his message to the Massachusetts legislature Governor Guild recommended a more general medical inspection of school children, especially for the discovery of infectious diseases and physical defects of eyes, ears or spines. He also called attention to the need of more accommodations for feeble-minded children, of whom a thousand have been refused by the institution at Waltham during the last six years, for lack of space.

Tuberculosis Exhibit a Success. The tuberculosis exhibit has been most successful. On several days more than 2,500 people visited it, and the interest increased up to the last day, January 7. As a result of the interest developed the new mayor of Boston, John F. Fitzgerald, has taken the first definite steps toward the provision of adequate hospital accommodations for those afflicted with this disease. One hundred and fifty thousand dollars was appropriated several years ago, but Mayor Collins insisted that this amount was insufficient. The present plan is to establish a board of unpaid trustees, to purchase land, an excellent site has already been selected, and erect temporary or inexpensive buildings. These have been proven to be entirely satisfactory in other tuberculosis hospitals. At present Boston provides only 50 beds for such patients and these are at the hospital on Long Island.

The Brigham Beneficiaries.—[ent] two charitable organizations received on January 1 their annual payment of \$1,000 each from the estate of Robert B. Brigham. They are: Massachusetts Charitable Eye and Ear Infirmary; Boston Associated Charities; Boston Dispensary; Boston Provident Association; Channing Home for Consumptive Women; Children's Hospital; Children's Mission to the Children of the Destitute; City Missionary Society; Home for Aged Men; Home for Aged Women; Massachusetts Infant Asylum; New England Home for Little Wanderers; Home for Aged Colored Women; Warner Home of St. Albans, in Vermont; Barnum Free Home for Aged Women; Home for Aged Couples; Boston Children's Aid Society; Boston Home for Invalids; Perkins Institute and Massachusetts School for the Blind; Massachusetts Society for the Prevention of Cruelty to Children; and the Boston Lying-in Hospital. The estate is rapidly increasing, and soon the land purchased on Parlor Hill, Roxbury, will be used for the great Brigham Hospital for Invalids. The site is one of the finest in Boston, and the plans for the hospital are partly formulated. Much effort has been made to have this institution wholly or chiefly for the consumptives of Boston, but it is not likely that such a plan will be adopted.

MICHIGAN.

Tri-State Meeting. The Northern Tri-State Medical Association of Michigan, Ohio and Indiana met in Detroit, January 9, in the Convention Hall of the Hotel Cadillac.

College Officers Elected. At the annual meeting of the Michigan College of Medicine and Surgery, Detroit, Dr. Hal C. Wyman was re-elected president for the nineteenth time. Dr. Dayton Parker, vice-president, and W. P. Holliday, secretary and treasurer.

Not the State Hospital. Dr. Blanch N. Epier, Kalamazoo, calls attention to an item in THE JOURNAL, December 16, regarding the Kalamazoo Hospital, and states that this institution has no connection with the State Hospital for the Insane, which is also located in Kalamazoo, and which has recently completed a ward at a cost of about \$60,000.

Personal. In memory of the late Dr. Louis Goldston, Houghton, a memorial room in the new hospital at Kalamazoo is to be dedicated to his memory. Dr. Beverly D. Harrison, Sault Ste. Marie, has moved to Detroit. Dr. J. C. Anderson, Grand Marais, has been re-elected physician of Alger County. Dr. Lucy M. Eames, Muskegon, has been appointed pathologist to the Hackley Hospital in that city.

Medical Aspect of the Social Evil. Under the auspices of the Wayne County Medical Society, a meeting was held in Detroit, December 18, to bring to the attention of laymen and physicians the dangers arising from venereal disease and the social evil. About 450 were present. The following excerpts will show the trend of discussion.

Dr. WILLIAM J. HERDMAN, Ann Arbor: "So grave is this danger that our physical, social, moral and a financial losses must be heeded to combat it."

Dr. C. R. BURR, Flint: "No more vicious aphorism ever gained foothold in the English language than that every young man must sow his wild oats."

Dr. HENRY O. WALTER, Detroit: "Gradual education along the lines of the disease surrounding them should be advanced to the people."

Dr. FLETCHER, Kalamazoo, Ann Arbor: "Although we have had a report on our books for over six years, making it a felony for not reporting cases of these diseases, not one case has been reported to the state authorities."

Dr. J. H. DE CARSTENS, Detroit: "Thorough education and the education of the sympathies would prove effective means of prevention."

Dr. ABBIE F. CARRIE, Detroit: "We don't begin to realize the danger to the community. It is about time we woke up to this danger."

DEAN THOMAS, of the Law Department of the University of Michigan: "It is a terrible evil that should arouse all citizens. It is not confined to any one class. It should be fought very largely through our educational system."

RUBEN LEO M. FENSTER, "It is a social problem rather than a problem of the individual. If the public is to count for anything, it must touch our present problem on its side."

Dr. VICTOR C. VANDER, Ann Arbor: "There are more good people in this world than evil, and when they pull together they can accomplish anything."

At the close of the meeting, Dr. William J. Herdman introduced a resolution, which was adopted, calling for the appointment by President Carter of the Wayne County Society, of a committee of six, who in turn will select a committee of twenty from all over Michigan, whose duty it will be to organize a state society to carry on the work.

NEW JERSEY.

Vital Statistics of the State.—The annual report of the State Board of Health shows a continued increase of marriages per 1,000 inhabitants for six years, from 1898 to 1903. There was a slight falling off in the rate in 1904. The rate last year was 13.38 per 1,000. The death rate per 1,000 increased to 17.14.

Camden Vital Statistics. The report of the Division of Vital Statistics of Camden for the year just ended shows that there were 1,652 births, 1,402 deaths and 2,338 marriages. This shows an increase of 469 marriages over those of last year. There was also an increase of more than 300 births and a decrease in the number of deaths of 130.

Personal. Dr. Emma M. Richardson of Camden was seriously injured in a trolley collision, December 22. — Dr. William F. MacLennan has been chosen city physician of Gloucester City. — Dr. E. L. B. Godfrey, Camden, secretary of the State Board of Medical Examiners, has been operated on for appendicitis in Pasadena, Cal. Dr. and Mrs. Godfrey left Camden about six weeks ago to spend the winter in California.

NEW YORK.

For Incubator Infants.—Senator Brackett has introduced a bill prohibiting the exhibition of infants during incubation.

State Charities. Governor Higgins, in his annual message, said that there had been steady progress of the state in its management of charities. More patients had been discharged from the state hospitals for the insane as recovered than in any previous year. The net increase of the state hospital population has been the lowest for any one year for the past fifteen. The census shows that in no other state of the union is such generous provision made for the care of the sick poor. Charitable institutions and hospitals for the insane cost the state about \$8,000,000 annually. The Craig Colony for Epileptics is in need of a large new building, and provision should be made for its construction. A commission has been appointed to inquire into the most practical methods of providing modern prison buildings.

Buffalo.

No New Marine Hospital. Because of the non-approval of the secretary of the treasury the intention to build a United States Marine Hospital at Buffalo at an estimated cost of \$125,000 has been abandoned.

Isolation Hospital for Children. With the bequest of the late Dr. De Villio W. Harrington of one-half of his estate, amounting to \$12,000, the managers of the Buffalo General Hospital intend to build a modern children's hospital for contagious diseases.

Widal Tests. Beginning January 1 the department of health has added the Widal test of the blood in suspected cases of typhoid fever to its laboratory work. These examinations are free. A specially designated Widal outfit is used and may be obtained at any police precinct station house in the city.

Personal. Dr. Harry Gaylord and wife have gone on an extended trip to Jamaica. — Dr. Duncan A. Carmichael has assumed charge of the United States Marine Hospital at Buffalo, vice Col. Cyrus T. Peckham, deceased. — Dr. L. Bradley Dorr has been elected president of the East Side Business Men's Association; Dr. Peter W. Van Poyma is also a member of the executive committee.

New York City.

Personal. Dr. and Mrs. Eugene Fuller arrived on the *Minneapolis*, January 2.

Low Death Rate. The death rate for the week ended December 30 was 18.03 per 1,000, as against 19.43 in 1904. Measles showed an increase. Bright's disease increased from 121 in the last week of 1904 to 113 in the last week of 1905.

The Yetkes Will. This document directs the trustees of the Yetkes galleries to purchase a proper plot of ground in the borough of the Bronx, and cause proper buildings for a hospital to be erected thereon, the aggregate cost of such ground and buildings not to exceed \$800,000. The income arising from another portion of the estate, which will amount eventually to more than \$7,000,000, is to be used for the maintenance of the hospital, which is to be opened to the public without regard to race, creed or color. Eventually the Yetkes Hospital will receive the shares of the estate set aside for the use of the son and daughter.

Officers of the Neurological Society.—The New York Neurological Society has elected the following officers for the year 1906: President, Dr. Joseph Fraenkel; vice-president, Dr. Adolph Meyer; recording secretary, Dr. Edwin G. Zabriskie; treasurer, Dr. Graeme M. Hammond, and corresponding secretary, Dr. Frank M. Hallock.

Absolute Power Over Milk Supply.—In the decision handed down in the Lieberman case in the United States Supreme Court it is stated that absolute power over the milk supply of the city is vested in the commissioner of public health. The handicap under which the department struggles is lack of funds. The board of estimate has allowed no more for this work during the coming year than for last year.

Needs of the City.—In his message Mayor McEllan stated that provision must soon be made by the city toward securing fresh-air homes for children and convalescents, as well as breathing space for the whole people. He especially recommended one of the beaches on the Long Island shore, and that in view of the importance of this matter to the general health of the city, the subject be seriously considered during the coming year.

Good Health of the City.—The records of the year show a marked decrease from the total number of deaths from all causes from the record of last year. There was an exception in the case of tuberculosis, where there is apparently some increase in the number of cases over former years; this increase was probably due to the fact that cases were more frequently reported. In 1905, 103,852 births were reported, as against 99,555 for the year previous. There were 73,450 deaths during the past year, as against 78,060 in 1904. The marriages reported number 42,667, while in the previous year there were only 39,436.

Report of the Charity Organization Society.—This society has just issued its twenty-third annual report from July 1, 1904, to Sept. 30, 1905. A special report of an investigation in regard to the purchase and management of food by 100 tenement-house families is of great interest. The report of the committee on the prevention of tuberculosis shows what the society is doing in this direction. The department of public charities maintained in its own hospitals during the past twelve months 3,959 patients, and paid for the maintenance of, on the average, 788 patients per month in private hospitals which care for the consumptive poor. This committee recommends as a result of its study that physicians and others do not send consumptives to the country to shift for themselves, for the reason that any scheme for the country employment of consumptives should offer facilities for the careful adjustment of work to the physical ability of each patient. This should be under medical supervision and should include instruction in the rudiments of farm work. A farm school in connection with a sanatorium would perhaps be an ideal arrangement.

OHIO.

The Johnstone Estate.—The personal estate of the late Dr. Arthur Weir Johnstone, Cincinnati, is appraised at \$16,354.46.

The Unfortunate.—Dr. George W. Quigley, North Amherst, has been committed to the Massillon State Hospital.—Dr. William J. Manning, Cleveland, was seriously injured in a runaway accident, December 26.

Military Notes.—Harry Hamilton Snively, Columbus, major and surgeon, O. N. G., has been appointed member of the board of medical examiners for the National Guard of Ohio, vice Major Cassius M. Shepard.—Dr. Rufus C. Pennywitt, Dayton, lieutenant and assistant surgeon O. N. G., has been commissioned captain and assistant surgeon.

Academy Election.—At the annual meeting of the Columbus Academy of Medicine, Dr. James U. Barnhill was elected president; Dr. Sylvester J. Goodman, vice-president; Dr. William C. Davis, treasurer; Dr. Charles J. Shepard, secretary; Dr. John A. Frame, censor, and Dr. John H. J. Upham, delegate to the legislation committee of the State Society. The academy presented Dr. David M. Kinsman, its first president, with a gold-headed cane.

Northwestern Ohio Physicians Meet. At the annual meeting of the Northwestern Ohio Medical Association held in Fremont, December 7 and 8, the following officers were elected: Dr. Albert S. Rudy, Lima, president; Drs. Robert H. Rice, Fremont, and Joseph H. Huntley, Lima, vice-presidents; Edwin A. Murbach, Archbold, secretary, and Dr. William S. Phillips, Belle Center, treasurer. The association will hold its 1906 meeting in Lima.

Personal.—Dr. and Mrs. Orlando T. Maynard, Elyria, start next month for Europe and the Holy Land.—Dr. Wiley D. Hickey has been elected mayor of Leipsic.—Dr. Read L. Bell has been elected president, Dr. James M. Austin, vice-president, and Dr. Emory F. Davis, secretary of the staff of Springfield City Hospital.—Dr. Olen E. Chenoweth has been appointed surgeon of the Detroit, Toledo and Ironton R. R., at Lima.—Dr. James Cutler, Richwood, has gone to California for the winter.

PENNSYLVANIA.

Personal.—Dr. Hamilton Graham, Kennett Square, has been elected president of the local board of health.—Dr. LeRoy K. Leslie, Bareville, has been elected president of the Lancaster City and County Medical Society.

Smallpox in Tamaqua.—The smallpox situation is serious in Tamaqua. An emergency hospital has been established and the board of health has ordered, in addition, that public schools and all places of amusement, churches, etc., be closed, and that all lodges and society meetings be discontinued. Door-to-door vaccination has been ordered.

Approve of Vaccination.—The physicians of Lock Haven, with one exception, deny the report that they were opposed to vaccination and, therefore, have sent the following letter to the *Philadelphia Press* over their signatures: "We, the undersigned physicians of Lock Haven, deny that any physicians in this city are opposed to vaccination or the law governing the same. R. B. Watson, E. P. Ball, George D. Green, W. J. Shoemaker, George W. Maust, J. S. McGinniss, R. Armstrong, William Armstrong, Joseph Hayes." The compulsory vaccination law is being enforced by the authorities in Lock Haven, and 676, or more than one-half of the total number of pupils registered, have been refused admittance.

Defy Vaccination Act. The local authorities of Waynesboro openly defied Dr. Dixon by resisting his vaccination order, and reopening the public schools January 2, admitting hundreds of unvaccinated children. The schools were closed for the holidays, but during that time nothing was done toward meeting the requirements of the compulsory vaccination law. Of the 1,200 pupils enrolled it is stated that 900 are not vaccinated, and a large proportion of the parents refused to submit to vaccination. Dr. Dixon conferred with the governor, attorney-general and superintendent of public instruction, and it was decided to commence mandamus proceedings against the board to compel the members to obey the law. Attorney-General Carson said: "We are going to enforce the law. We are not going to countenance such defiance, and if the mandamus does not work, then we will proceed under the penal clause of the law."

Philadelphia.

Personal.—Dr. Andrew J. Muller was appointed an assistant medical inspector by Director Coplin in the place of Dr. Henry C. Sibletham, resigned.

Bequests.—By the will of the late Hugh Leonard, St. John's Orphan Asylum receives \$1,000.—A bequest of \$5,000 to the Pennsylvania Hospital for the endowment of a free bed for a woman patient was contained in the will of the late Anne E. Peale.—A bequest of \$7,000 for the Friends' Asylum for the Insane was contained in the same will, and also \$1,000 to the Pennsylvania School for Feeble-minded Children, and \$300 for the Methodist Church Home for Children.

Health Report. The total number of deaths reported for the week ended January 6 aggregated 536, which compares unfavorably with 491 reported last week, and with 478 reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 19; measles, 19; diphtheria, 19; consumption, 46; cancer, 30; meningitis, 3; apoplexy, 18; heart disease, 44; acute respiratory disease, 88; enteritis, 27; appendicitis, 6; Bright's disease, 31; suicide, 4; accidents, 18, and marasmus, 7. There were 341 cases of contagious disease reported, with 46 deaths, as compared with 262 cases, with 23 deaths, reported in the previous week. There were 353 cases of measles reported and 197 new cases of typhoid fever.

New Officers.—At the annual meeting of the College of Physicians, January 3, the following officers were elected: President, Dr. Arthur V. Meigs; vice-president, Dr. James Tyson; censors, Drs. Richard A. Cleemann, S. Weir Mitchell, Horace V. Evans, and Louis Starr; secretary, Dr. Thomas R. Neilson; treasurer, Dr. Richard H. Harte; honorary librarian, Dr. Frederick P. Henry; censors, Drs. J. Allison Scott and Francis R. Packard.—Dr. Wendell Reber was elected chairman, and Dr. William H. Park, clerk, of the North Branch of the Phila-

Delphia County Medical Society at the December meeting.—Dr. Royal W. Benis was elected chairman, and Dr. Cyrus C. Moore, clerk, of the Kensington Branch of the same society, at the December meeting.

Vital Statistics Registrars.—The state commissioner of health, Dr. Samuel G. Dixon, has appointed 950 local registrars for the collection of vital statistics for the State Department of Health. The appointments were made December 24, and the men will be directed to begin work on January 1, when the new state law goes into effect. The registrars will receive 25 cents for each birth and death they report. They will also receive 25 cents for each monthly report of any deaths or births for any month. They are entitled to a fee of 50 cents for each disinterment permit issued by them, the fee to be paid by the person receiving the permit. Under the law creating the bureau of vital statistics, the local registrars who fail to perform their duty may be removed by the state health commissioner, and be further deemed guilty of a misdemeanor and on conviction be punished by a fine of not less than \$10 nor more than \$100.

Lectures on Tuberculosis.—The lectures on tuberculosis at the tuberculosis exposition, to be held from January 22 to February 3, will be delivered by the following: January 23, Dr. Lawrence F. Flick, "The Sociological Importance of Tuberculosis"; January 24, Dr. Leonard Pearson, "State Control of Tuberculosis"; January 25, Dr. Charles Dudley, Altoona, "The Railroad in Tuberculosis"; January 26, Dr. William B. Stanton, "Tuberculosis in the School"; January 27, Dr. Howard S. Anders, "Tuberculosis in the Store"; January 29, Dr. Henry R. M. Landis, "Tuberculosis in the Workman"; January 30, Dr. Samuel McC. Hamill, "Tuberculosis in Children"; January 31, Dr. Thomas Darlington, New York City, and Dr. W. M. Late coplin, "Municipal Control"; February 1, Dr. Charles J. Hatfield, "Address to Medical Students and Nurses"; February 2, Drs. James C. Wilson and John H. Musser, "Address to Physicians," and February 3, Dr. M. P. Ravenel, "Hospitals, Sanatoria and Dispensaries." Demonstrations on pathology will be given from 2 to 6 daily.

VIRGINIA.

Burnt Out.—A recent fire gutted the office of Dr. Barksdale Hales, Fredericksburg, causing a loss of \$1,500.

Medical Colleges Not to be Consolidated.—All hope of consolidating the Medical College of Virginia with the Medical Department of the University of Virginia has been given up. At a joint meeting of the committee just held it was found impracticable at this time for the amalgamation to be consummated. While the supreme end of union has not been reached, the long-existing friendship of the two institutions has been strengthened.

South Side Meeting. The South Side Medical Association held its tenth annual session in Petersburg. The following officers were elected: President, Dr. E. F. Reese, Courtland; vice-presidents, Drs. Joel Crawford, Yale, B. Barrow, Barrow's Store, and J. W. Baird, Corsley; Dr. J. H. Hargrave, Garysville, secretary, and Dr. R. L. McNair, Emporia, treasurer. Emporia was selected as the next place of meeting in March, 1906.

Richmond Academy of Medicine and Surgery. The election of officers for this society resulted as follows: Dr. Ramon D. Garvin, president; Drs. J. Fulmer Bright, Ernest C. Fisher and M. P. Rucker, vice-presidents; Dr. Mark W. Peyer, secretary, and Dr. A. I. Sheppard, treasurer. The installation of officers will take place in January, when the annual banquet will be held and steps will be taken looking to the purchase of a home for the academy.

GENERAL.

Harvey Society Lecture. The fifth lecture in the Harvey society course will be given by Prof. W. H. Park at the New York Academy of Medicine on January 20, at 8:30 p. m. The subject will be, "A Critical Study of Serum Therapy."

New Hospital in Manila. St. Paul's Hospital in Manila, near its renovation, is one of the best equipped in the far East. The hospital can now accommodate 150 patients. There are native wards and wards for Europeans. There are also three wards for Americans. There is a well equipped operating room fitted with all modern appliances. Dr. John R. McGill is surgeon in chief; Dr. W. F. Macnave, physician in chief, and Dr. Paul G. Woodley, pathologist.

The Medal of Honor Given Dr. Church. The President, January 10, in the presence of the secretary of war, the chief of

staff, and the surgeon general of the Army, presented a medal of honor to Capt. James Robb Church, assistant surgeon, U. S. Army, for gallantry in action at the battle of Las Guasimas, Cuba, on June 24, 1898. The award of this medal was announced in THE JOURNAL, Dec. 30, 1905, and a brief sketch of Dr. Church given. The delay in giving this medal is understood to be due to a failure on the part of his superior officers in recommending Dr. Church for this honor, to conform exactly to certain technical requirements of the regulations governing its award. Gen. Leonard Wood, who commanded the Rough Rider regiment in that fight, was, however, unwilling to let technicalities stand between conspicuous merit and its reward, and succeeded in interesting the authorities at the War Department in the matter, with the result above stated. Dr. Church has, however, lost nothing by the delay, as he becomes thereby the first beneficiary of the executive order issued last September requiring that the presentation of medals of honor thereafter shall be with formal and impressive ceremonial, if practicable, by the President in person. Dr. Church is at present stationed at Fort Robinson, Neb.

Health Report of the Philippines for August.—In the official report for August, 1905, the reappearance of cholera in and around Manila is discussed at some length. From time to time during the year, it is stated, cases which clinically resembled Asiatic cholera came to the attention of the Board of Health, but the diagnosis could not be verified bacteriologically. For the two weeks preceding August 23 the number of suspicious cases was increased. One occurred at San Pedro Macati, one in a bakery in Paco, one in the San Miguel district, one case was that of a soldier in Cuartel de España, and it is now known that a number occurred in Rizal province. It was not until August 23, however, that a case developed in Bilbid prison, which was later found by laboratory examination to be cholera. On the following day six cases of suspected cholera were registered at Fort McKinley. An extra session of the board of health was held, after which Dr. Freer, Dr. Strong and Dr. Heiser, on the invitation of the medical officer in charge, proceeded to the fort to make an investigation of the nature of the disease which had made its appearance in so unexpected a manner. After examining the cases, it was impossible to state positively that they were cholera, although the consensus of opinion was that they were very suspicious. No material could be obtained for a microscopic examination. Several days later, however, the diagnosis was bacteriologically confirmed. On August 25 an American woman residing at the Grand Hotel, Walled City, was attacked, and also a man, who had arrived in the city the night before from Bataan province and had taken lodging at the house of his brother, Calzada de San Sebastian. It was learned later that this man was not absent from the city, on his Bataan trip, more than forty-eight hours. Both patients were removed to the cholera hospital at San Lázaro. A telegram received on August 26, from Jalajala, through the army medical department, contained the following information: "Cases of a disease resembling cholera have developed in Jalajala, the first case being registered August 21; from that date to August 25, 16 cases and 12 deaths have been registered, the illness lasting from twelve to twenty-four hours." On that same date the provincial president of the board of health of Rizal reported, by wire from Pasig, one suspicious case, followed by death, in that town. On the following day the death, from cholera, of a nun in the monastery of Santa Clara, Manila, was reported to the health office. At that convent the most rigid regulations are observed, and communication with the outside world is reduced to a minimum. As this was rather an unusual case, a full and accurate statement of the facts concerning it was secured, and, among other things, it was ascertained that it was the nun who was in charge of the infirmary who had taken the disease. The infirmary is located far inside the building, where there would be very little probability of its coming in contact with anything from the outside. The day of her death the nun felt indisposed and took a laxative from the dispensary of the convent, apparently recovering. After the noon meal she ate some lanzones, supposed to have been taken from a tree in the orchard of the convent, and a few hours later, early in the afternoon, she was taken ill with the disease, dying between 8 and 9 of that evening, with all the symptoms of cholera. No other case occurred in the convent. In the meanwhile other cases were being registered from nearly all the districts of the city, although the number of cases was not very great, as may be seen by the report. From August 23 to 31 only 51 cases and 46 deaths were recorded. In this review of the outbreak it is stated that no effort has been made to draw any definite conclusions, the only aim having been to state certain facts which may be use-

ful later in making further researches into the origin of the disease. The report gives in detail the means adopted to prevent the spread of the disease. During August there were 903 deaths, of which the greatest number were caused by pulmonary tuberculosis, dysentery and cholera. Six hundred and fifteen births were registered during the month (a birth rate of 32.93 per thousand); of these 322 were males and 293 females.

CANADA.

Smallpox in Ontario.—There are over 20 cases of smallpox in the village of Dundalk, Ontario.

Prevalent Diseases.—An epidemic of typhoid is reported from Phoenix, B. C.—Eighty-four cases of smallpox are reported in the county of Dufferin, Ontario, but no deaths.

Ontario Medical Council.—The present building of the Ontario Medical Council has been sold for \$100,000, and a new one will be erected at once for the council purposes alone.

Death Rate of Vancouver.—The death rate of the city of Vancouver, B. C., for November, 1905, the total number of deaths being 24 in an estimated population of 42,000.

Typhoid in British Columbia.—The provincial health department of British Columbia is taking active steps to suppress the typhoid fever epidemic in certain interior districts of that province.

Vital Statistics of Toronto.—There were 533 more births in Toronto in 1905 than in 1904. The marriages increased 277 and the deaths 33. The total number of births were 6,816; marriages, 3,060; deaths, 3,915.

Tuberculosis Camp.—The Montreal League for the Prevention of Tuberculosis has asked the city council for a grant of land and for financial aid for the purpose of installing near that city a temporary camp for consumptives.

Paying Patients in Insane Hospitals.—The Ontario government has adopted a vigorous policy with regard to the revenue from paying patients in the provincial hospitals for the insane. For years there have been many delinquents, but as the result of the inauguration of this policy the revenue from this source increased in the last four months by nearly \$30,000.

Personal.—Dr. Mary McKenzie, Pietou, N. S., who was graduated from the Halifax Medical College last spring, has gone to India under appointment from the Woman's Union Missionary Society of America. Her hospital work will be in Cawnpore.

—Dr. R. C. Hiseock, Kingston, Ont., has been appointed government health inspector with headquarters at Lagos, West Africa. —Dr. McLennan, a native of Cape Breton, Canada, is court physician to the king of Tonga Island in the Pacific Ocean. —Sir James Grant, M.D., Ottawa, has issued in book form the lectures he delivered on tuberculosis in Scotland during last summer. —Dr. R. H. Richards of Winnipeg has sailed from Vancouver for a three months' trip to Honolulu and Australia. —Dr. Eliezer Pelletier, secretary of the provincial board of health of Quebec, has returned to Montreal after attending the recent congress on tuberculosis in Paris.

Hospital News.—The Toronto General Hospital fund now amounts to \$1,000,000.—The total number of patients treated in the Winnipeg General Hospital during the week ending December 16 was 395; of these, 253 were men, 82 women and 60 children.—The grand jury of the County of York, Ontario, has advised that a new provincial hospital for the insane is needed for the city of Toronto, and recommends that a site of 300 acres be purchased adjacent to the city.—The dominion government is calling for tenders for the construction of a hospital at Lawlor's Island, N. S.—The ratepayers of Winnipeg have voted favorably on a by-law to grant \$150,000 for hospital purposes.—The Medical Faculty of the University of Toronto has contributed \$50,000 to the Toronto General Hospital.—The Hamilton (Ontario) board of health is advising new isolation and smallpox hospitals for that city.—A fine new general hospital has just been completed at Vancouver, B. C. Fire destroyed one of the cottages for female patients at the Mimico Provincial Hospital for the Insane, near Toronto. The loss was \$15,000. All the patients were safely removed.

On November 30 there were 302 patients in the Toronto General Hospital. During December 279 were admitted, and 310 discharged, leaving 271 patients in the hospital on Jan. 1, 1906. —During the week ending December 30, 349 patients were treated in the Winnipeg General Hospital.

Ontario Vital Statistics. The total number of deaths occurring in Ontario during November was 2,011, or 108 more than

were reported in November, 1904. The death rate for the month is 12.3 per 1,000 of the population, as compared with 12 of last year. Throughout the province smallpox still continues on the increase, although it is of a mild character. During the month there were 182 cases, with no deaths, whereas in November, 1904, there were only 2 cases, with no deaths. There were 104 cases of scarlet fever; 249 cases of diphtheria, with 28 deaths; 203 cases of typhoid fever, with 55 deaths, and 128 cases of tuberculosis, with 128 deaths. November, 1905, had the largest number of cases of smallpox since January, 1903, when there were 196 cases and 10 deaths.

National Sanitarium Association's Annual Meeting.—The eighth annual meeting of the National Sanitarium Association was held in Toronto, December 16. Dr. J. H. Elliott, physician in charge of the Muskoka Cottage Sanitarium, made his annual report and stated that during the course of the last official year there were 233 patients under treatment. These had come from all parts of the Dominion of Canada and some from the United States. He advised that the sanitarium be increased in size to accommodate an additional 100 patients. Speaking of those who had been discharged from seven to eight years ago, Dr. Elliott stated that all those apparently cured who could be traced were perfectly well, and in the arrested cases 70 per cent. remain well. Dr. C. D. Parfitt, physician in charge of the Muskoka Free Hospital for Consumptives, presented the report of that institution, which showed that 153 patients had been admitted during the year, while the number of patients treated during the year had been 218. Thirty-seven of these were charity patients from Toronto. The accommodation at this hospital has recently been increased to 75.

FOREIGN.

Governmental Control of Leprosy in Japan.—It is reported that at the approaching session of the imperial diet legislation will be proposed with a view to governmental control of leprosy in Japan.

Physicians in Parliament.—Twenty-two physicians are among the candidates for the next elections to parliament, according to our British exchanges. In Italy, Grocco of Florence has recently been appointed senator. There are now 8 medical men in the Italian legislature, 5 senators, Grocco, De Renzi, Cardarelli, Maragliano and De Giovanni, and 3 deputies, Baccelli, Rummo and Queirolo. Rummo is editor of the *Riforma Medica* and Maragliano of the *Clinica Medica*. All are professors in some medical faculty.

Anthrax in China.—Acting Assistant Surgeon Ransom, at Shanghai, reports that a case of "internal anthrax" occurred at Hankau, Nov. 25, 1905, in an office employee of one of the hide companies. This is the only case of the kind which has recently occurred within the knowledge of the officials at that place. The matter is interesting in that a large percentage of the hides shipped to the United States from China come from the vicinity of Hankau; none, however, are allowed to pass Shanghai unless accompanied by a consular certificate of arsenical curing.

Plague in Japan.—Dr. Moore of the Public Health and Marine-Hospital Service reports that the plague situation in Kobe and Osaka shows no evidence of marked amelioration and that the present outbreak bids fair to prove one of the most formidable manifestations of this infection that has yet visited Japan, excluding Formosa. The American consul at Kobe, he states, has formally declared Kobe and Osaka to be infected ports. There is reason to believe that several of the larger steamship companies plying between Kobe and the United States will decline for the present to sell storage tickets from that port to the United States under existing circumstances.

Silver Jubilee of Tidsskrift f. d. Norske Lægeforening.—This journal is the official organ of the Norwegian Medical Association. It is published at Christiania and has just completed its twenty-fifth year. To signalize the occasion it gives the portraits of each of its editors and general secretaries during its career, with breezy articles from the pens of each on the *Tidsskrift* in their day, or historical sketches of those who have died. The present editor and the general secretary are Drs. P. Aaser and R. Hansson. The number also contains an article on "Difficulty in Removing the Tube after Intubation," with radiograms of cases, and, as usual, a number of articles on local medical questions, insurance against sickness, sanatoriums, antiquary movement, etc.

Congress Katzenjammer. Under this suggestive heading Aischel describes in the *Prog. med. Wochs.* for December 7, his impressions "the day after" the Tuberculosis Congress at Paris. He remarks that it was the most poorly organized

congress that he had ever attended, and he suggests a number of reforms which he thinks are necessary if international congresses are to be of any value to science. Instead of wasting money on entertainments and banquets, etc., the appropriations for this purpose should be devoted to making up the deficit from the smaller membership when only truly interested scientific men are attracted to the congress. As it is now, every effort is made to increase the attendance to cover the expenses. Alstedt suggests further that a publisher could surely be found to publish the transactions and supply a copy free to each member if given permission to place the remaining volumes on the market. The main purpose of an international congress is the interchange of opinions, and this can not occur when sections are multiplied and too many subjects and communications allowed. Too much time is wasted in international congresses on discussions of purely local questions. It is refreshing to turn from this arraignment to Sonnenburg's enthusiastic commendation of the recent International Surgical Congress (*Berliner Klin. Wochts.* No. 44, a.). Every detail of this congress might serve as a model to all others, he exclaims. It was described in these columns on page 1180 of the last volume. Instead of being merely an opportunity for young fellows to disport themselves in public, it was devoted to a fruitful interchange of opinions between mature, experienced minds, on a limited number of vital themes.

International Antiquackery Campaign.—The first officially organized society for the repression of quack practices was the "Vereniging tegen de Kwakzalverij," which was founded in Holland twenty-five years ago. The occasion for its founding is said to have been the extensive advertising throughout the country of Ayer's sarsaparilla, pain expeller, etc. The society recently celebrated its twenty-fifth anniversary. Treub of Amsterdam delivered an address on "Quack Practices," and J. M. van Elk of Zutphen, Holland, one on the "International Antiquackery Campaign." The latter referred to Henry Graack's recent compilation of the laws and regulations affecting the practice of medicine and quack practices in Germany and elsewhere. He expressed the hope that this important work may be the source of fruitful study for legislators and others in Europe and throughout the world. He remarked that although the laws of Holland still leave much to be desired, they have certain model features. Unfortunately, they are not enforced, and any one can assume the title of "Dr." at will. He referred to the comeliness of the lay press in the advertising of quacks and nostrums, and declared that the various governments are not yet convinced in regard to the tremendous evils of quack practices and nostrums. It should be the task of the various antiquackery organizations to enlighten legislators in this respect. When the governments are once convinced, then an international antiquackery conference should be organized. The board of health of Karlsruhe and its brave mayor have been working for years along this line. They publish the analysis of various secret remedies advertised, showing the way in which the public is being swindled out of its money. (Their work has been previously described in THE JOURNAL.) Sweden has also a well organized antiquackery society under the leadership of Dr. T. Thunberg and Prof. C. T. Mörner. Efforts are being made also in other countries, but unfortunately, so far the organizations stand alone, and lack the benefits and strength of international support. International organization and co-operation are imperatively needed. Associations should be formed with local branches everywhere, all co-operating in collecting data and holding conferences occasionally for discussion of ways and means. The first thing to be done, he continued, is to make the press responsible for quack advertisements. If the papers were held responsible for injury resulting from such advertisements, these would soon disappear from their columns; but this, van Elk believes, must be done internationally. It would be little good if the newspapers of Holland, for instance, were to refuse to take these advertisements, as the quacks would simply transfer their advertisements elsewhere. Another important point, he added, is to have severe penalties imposed on persons distributing false medical pamphlets and circulars. The police should be empowered to suppress their distribution, but this will not prove effective unless the measure is international. The practice of medicine should be restricted to qualified persons, and the present free-for-all allowed to any one to practice "nature healing," etc., should be withdrawn. It should also be strictly forbidden to recommend to sell or to hold in stock any remedy for which the true and exact formula is not printed on the wrapper in popular language. Then only will the public know what it is buying. The giving of a false or incomplete formula should entail a severe penalty. There too a nation should be interna-

tional, so that, for instance, the German court should impose a penalty in Germany on the manufacturer of a remedy made in Germany to be sold in another country, and *vice versa*. The German Antiquackery Society sent Rumpe of Krefeld and C. Reissig, the editor of its official organ, *Hygienische Blätter*, as representatives to the jubilee meeting, and van Elk greeted them as announcing the dawn of an international era in the campaign against the many-headed hydra of charlatanism. Before the meeting adjourned the nucleus for an international antiquackery committee was organized. The members appointed are Lind, van Gelder, Treub and van Elk, of Holland; Rumpe of Krefeld, and C. Reissig, Hamburg 5, of Germany. The *Hygienische Blätter* is published by E. Grosser, Berlin, Wilhelmstrasse 121. Subscription 1.5 marks a year, or about 50 cents, including postage. Most of the above report of the Holland meeting is translated from its December issue.

Prizes Offered by the Paris Académie de Médecine.—The French are particularly fond of the endowed prize, and the Paris Académie de Médecine has fifty at its disposal, which are open to the competition of the world. Most of them are annual, but others are biennial and even quinquennial. The prizes are awarded early in December of each year, the lists being closed by February of the current year. Competing works must be in French or in Latin. All the prizes this year were given to physicians residing in France or its colonies, with the exception of the Godard prize of \$200, given to Dr. Faxton E. Gardner of New York City for a work entitled "Plastic Operations and Anastomoses in Treatment of Renal Retention," and \$120 to Dr. S. R. Hermandes of Zeist, Netherlands, for a work on the parasymphilitic affections. Franceschini of Vienza, Italy, and Pawinski of Warsaw also received honorable mention. Cristiani of Geneva received part of a prize for his work on thyroid grafting, and also Remlinger, director of the Pasteur Institute at Constantinople, for his works on rabies. THE JOURNAL for Jan. 14, 1905, page 138, commented on the fact that so few physicians from America compete for these prizes. Full details of competition were given in THE JOURNAL for Jan. 24, 1903.

The prizes for which competing articles must be sent in with the author's name in a sealed envelope are the Académie prize of \$200 (in 1906), for the best work on the pathogenesis of pulmonary edema; (1907), on the physiology and pathology of the suprarenal capsules, and (1908), on the etiologic and clinical relations between syphilis and neoplasms and neoplasms and syphilis; the Capuron annual prize of \$160 for the best work on any branch of medicine; the Capuron annual prize of \$200, (1906), on the gases in certain designated mineral waters, (1907), on relations between menstruation and ovulation, and (1908) on the detachment of the placenta during the last two months of pregnancy and during childbirth; the Civrieux annual prize of \$160 (1906), for the best work on acute encephalitis (1907), on spinal syphilis, and (1908), on homoclinic in mental pathology; the Faurel annual prize of \$200 (1906), for the best work on x-ray treatment of cancer (1907), on evolution and prognosis of epitheliomatous tumors of the ovary, and (1908), on melanotic sarcomata; the Faurel biennial prize of \$140 (1907), for the best work on the mental condition in dipsomania; the quadrennial Herpin prize of \$240 (1906), for the best work on the abortive treatment, either at debut or during incubation, of affections caused by trypanosomas; the Lefevre triennial prize of \$360 (1908), for best work on melancholia; the Louis triennial prize of \$600 (1907), for best work on radiotherapy of neoplasms; the Mège triennial prize of \$180, (1907), on etiology and pathogenesis of phlebitis; the Orfila biennial prize of \$400 (1906), for best work on purification of water used in cities and of the residues of water in the treatment of the central nervous system; (1906), for best work on thyroid neoplasms, pathologic anatomy and pathogenesis (1907), on leukemias, and (1908) on the blood and blood-forming organs in pernicious anemia, and, finally, the "Boussingault" prize of \$400 (1906), for the best work on the entrance into play in diseases; (1907) on experimental study of sensory, motor and vascular innervation of the larynx, and (1908), on the modifications of pressure which occur in the cavities of the heart during the ventricular pause and the causes which determine these modifications.

Articles competing for all the above must be sent in anonymously. In addition to these there is a long list of prizes to be awarded for either manuscript or printed works.

They include the Amussat prize, \$200 (1908), for surgical therapeutics; the Audebiert annual prize, \$120, for electrotherapy; the Balthazard biennial prize, \$400 (1906 and 1908), for study of treatment of mental affections and organization of insane asylums; the Barbier annual prize of \$100 for a complete cure of some disease hitherto deemed incurable. This prize can be apportioned to encourage workers in this line; the Bozzio triennial prize of \$850 (1907), to encourage and reward studies to find a cure for tuberculosis; the Boullard biennial prize of \$240 (1906 and 1908), for the best work on the best means, in arotherapeutic, attending or curing mental affections; the Bourgeois annual prize of \$200, on best work on circulation of blood; the Buisson triennial prize of \$2,100 (1907), for best discoveries having for result the cure of some affection hitherto deemed incurable; the Campbell-Duperris biennial prize of \$1,000 (1906 and 1908), for best work on diet, natural history and therapeutics; the Godard annual prize, \$200, for best work on internal pathology (1906), external path-

ology (1907), internal pathology (1908). The P. Guzman prize is an income of about \$266 at 3 per cent., which will be given for the discovery of a truly effectual treatment of some common form of organic heart disease; the T. Herpin prize of \$600, annual, for the best work on epilepsy and nervous diseases; the Iluzo prize of \$200 is given every five years, in 1906 for best work on some point in the history of the medical sciences; the Hard triennial prize of \$150, for best book on practical medicine or applied therapeutics; the Jacquemier triennial prize \$340 (1907), for work on some obstetrical subject which shall have realized an important progress; the Laborie annual prize of \$1,000 for the author of a notable and not yet the subject of surgery; the Larrey annual prize of \$100 for best work of medical statistics; the J. Lefort prize of \$60 (1908), for best study of mineral waters; the H. Lorquet annual prize of \$60 for best work on mental affections; the Mevot annual prize of \$75 for best work on affections of eyes (1907), and of ears (1906-1908); the A. Morin five-year prize of \$400 (1908), for the best work by physician under 30 on cure of diphtheria; the Nativelle annual prize of \$60 for extraction of active principle, not yet the subject of some drug; the Fobollet prize of \$100, \$240, bernia (1908); the P. Ricord biennial prize, \$120 (1907), for best work that has appeared during the two years on venereal diseases; the Saintour biennial prize of \$880, for best work on any branch of medicine; the Stanski prize of \$280, biennial (1906 and 1908), for demonstration of existence or non-existence of miasmatic contagion by infection or by distance contagion, studied in epidemics in general or in some special epidemic; the Stokley prize of \$140, for the best work on any epidemic; the best article on affections of the urinary passages, catarrh of the bladder or some affection of the prostate, and the Vernois annual prize of \$140 for best work on hygiene.

In addition to these prizes there is the great Andiffred endowment, representing an income of 24,000 francs, or \$4,800, to be given to the person who, before April, 1921, discovers a sovereign preventive or curative remedy for tuberculosis. The *Bulletin de l'Académie de Médecine*, No. 41, 1905, gives the full particulars of all these prizes. Copies can be obtained from the publishers, Masson et Cie, 120 boulevard Saint-Germain, Paris. It is a pity that more Americans do not compete for these prizes. No article can be entered into the competition for more than one prize in the same year. The trouble of having their article translated into French has undoubtedly deterred many Americans from competing, but this could easily be arranged at comparatively small expense. Address all communications for the Académie to the secrétaire perpétuel, Académie de Médecine, 16 rue Bonaparte, Paris. In this connection we might call attention again to the official information bureau at Paris, the "Bureau des Renseignements Scientifiques" à la Sorbonne. It is in charge of Dr. Blondel.

LONDON LETTER.

The London School of Clinical Medicine.

In recent years something has been done to remove from London the reproach of being alone among the capitals of the world in making absolutely no provision for postgraduate teaching. It is now proposed to use the Dreadnought or Seamen's Hospital at Greenwich as a postgraduate school, to be termed the London School of Clinical Medicine. The scheme has received considerable support from some of the most influential members of the profession in the metropolis. The following staff has been constituted: Physicians, Sir Dyce Duckworth, Dr. Frederick Taylor, Dr. Rose Bradford, Dr. R. T. Hewlett and Dr. Guthrie Rankin; surgeons, Sir William Bennett, Mr. Mayo Robson, Mr. A. Carless, Mr. Whiam Turner and Mr. McGavin; ophthalmic surgeon, Mr. V. Gargill; dermatologist, Mr. Malcolm Morris; laryngologist, rhinologist and otologist, Dr. St. Clair Thomson; electrotherapist, Mr. Mackenzie Davidson; stomatologist and dentist, Mr. Kenneth Goadby. These men will each receive a certain number of beds and take an active part in teaching. In this way the large and varied clinical material of the hospital will be made available for instruction. A special feature of the school will be exceptional opportunities for acquiring skill in operative surgery afforded by the relatively large number of unclaimed bodies which can be utilized for the purpose. Negotiations are in progress with various special hospitals, with a view of making the teaching of the London School of Clinical Medicine complete in every detail. It is intended to equip it with labora-

The Decline of the Birth Rate.

At the Royal Statistical Society two important papers were read on the decline of the birth rate. The first was by Drs. A. Newsholme and T. H. C. Stevenson. In the course of the paper the term "corrected birth rate" was introduced and was defined as a rate-making allowance for the fact that some populations include a much larger proportion than others of wives at a certain age, and taking into account both the ages and numbers of wives. This corrected rate gives different figures to the "crude birth rate." For instance, the crude birth rate of Ireland in 1903 was 23.1, which is only a little higher than that of France in 1902 (21.7); but correction practically

unaffected the French birth rate, whereas the Irish was increased to no less than 36.1, showing that the Irish fertility was nearly twice that of the French. This remarkable result is due to the fact that although both countries had approximately the same proportion of women, aged from 15 to 45, in their populations, 52.5 per cent. of those in France are married, as against 32.5 per cent. in Ireland. The greatest decline of fertility among the countries studied during 1881 to 1903 was shown by the following: England and Wales, 17 per cent. decline; New Zealand, 18 per cent.; Belgium and Saxony, each 24 per cent.; Victoria, 25 per cent.; and New South Wales, 33 per cent. Ireland alone showed an increase of fertility, 3 per cent. The authors arrived at the conclusion that the decline is associated with a general raising of the standard of comfort, and is an expression of the determination of the people to secure this greater comfort. This gospel of comfort is becoming the practical ethical standard of a rapidly increasing number of civilized communities. They have no hope that any nation—in the absence of strong and overwhelming moral influences to the contrary—would be permanently left behind in this race to deplete the "race," and they anticipate as a result a deterioration of the moral, if not also of the physical nature of mankind. The second paper was read by Mr. G. U. Yule. He stated that a comparison of the fertilities of married women in different districts of London in 1871 and 1901 showed that, while in the upper class districts the fertility had dropped by about 20 per cent., in the lowest class districts it was practically unchanged. It must, however, have fallen among the working classes in general, for the fall in the upper class districts is little more than for the country at large. A careful examination of fluctuations in the birth rate shows that it appears to respond, like the marriage rate, to the cycle of trade and industry.

The Use of Boric Acid as a Food Preservative.

The difficulty experienced in the courts in deciding as to the legality of the use of boric acid as a preservative in milk (reported in a previous letter) is also arising in regard to other articles of diet. The use of food preservatives is becoming more and more widespread. A firm of provision merchants was summoned for selling sausages containing 41 grains of boric acid to the pound. In the course of three hours' hearing a large number of experts were called on each side—those for the prosecution arguing that boric acid is a "foreign ingredient," prejudicial to the purchaser; and those for the defense contending that this is not so, as the acid is used as a preservative and is harmless. A. Stokes, an analyst, who was called by the prosecution, admitted that perhaps a tenth of all the samples he analyzed contained boric acid. Tinned fish and paste contain it and it is used for washing the fish on the fishmongers' stalls. Three-fourths of the butter imported into this country contain boric acid, though not to the extent of 41 grains a pound. No steps have been taken to prevent this. Mr. J. Douglas, another analyst, stated for the defense that boric acid is a usual ingredient of preservatives. "Borax" is made for sausages from boric acid. Without a preservative, sausages made with meat and bread only would not keep two days, even though the meat was the best and fresh. Dr. F. W. Tunnicliffe, a member of the departmental committee of the Royal Commission of Agriculture, said that there are many preservatives, the strongest of which is formalin, 1 part in 20,000 of which is effective. If formalin were used for meat in proportions similar to boric acid, the meat could not be digested. Mr. Chier, the magistrate, remarked, that butchers washed meat with formalin and then it would keep two months. Dr. Tunnicliffe remarked that one sometimes got a sole which was tough and had been treated with formalin. This was known as a "formalin sole." "A reasonable man," said the magistrate, "ought not to eat more than 2 sausages." That would include 12 grains of boric acid. The evidence for the prosecution was that 41 grains would be injurious, but possibly if a man ate a pound of sausages he would suffer more from them than from the boric acid. Dr. F. J. Smith, physician to the London Hospital, said that he had prescribed 10 grains of boric acid three daily for an adult without harm. Drs. J. P. Bate and H. R. Kenwood, both health officers, and the latter lecturer on public health at University College, expressed the strongest opinions that boric acid is injurious to health. Dr. Kenwood pointed out that, although the amount of boric acid in the sausages might not be shown to be injurious, if a man were taking also boric acid in his milk, meat, fish and preserves, the possibility of poisoning is obvious. He could not understand why boric acid is forbidden in milk and not forbidden in butter.

Pharmacology

PHENALGIN—A TYPICAL EXAMPLE.

Last June¹ we devoted considerable space to the extravagant therapeutic claims made for "Phenalgine" by its vendors. At this time we propose to refer to the misinformation—to use a conservative term—that the Etna Chemical Company has promulgated regarding the composition of their preparation.

Last June the Council on Pharmacy and Chemistry officially published to the medical profession of the United States the information that repeated examinations showed that "Phenalgine" is a simple mixture of acetanilid and sodium bicarb. or ammonium carb. So far as we know, no direct denial of the truth of this has been made. There has appeared what we presume is meant as an answer; it is couched in this sentence:

"PHENALGIN IS JUST WHAT WE HAVE ALWAYS SAID IT TO BE."

From this expression—which has been repeated in bold, black letters in practically all the advertisements since last June—we presume that we are to understand that in the past they have stated what it is.

It would have been just as easy and more satisfactory if the Phenalgine people, instead of saying: "Phenalgine is just what we have always said it to be," had said what it is, since the average physician has neither the time nor the inclination to look up their literature.

For the benefit of those who desire to know what the vendors of Phenalgine "have said it to be," we have gone over their advertising literature of the past, with the following results, which are in the form of quotations from their advertisements:

"AN AMERICAN COAL-TAR PRODUCT—PHENALGIN—THE ONLY SYNTHETIC STIMULANT, NON-TOXIC, ANTI-PYRETIC, ANALGESIC AND HYPNOTIC."

"PHENALGIN IS THE ONLY AMMONIATED SYNTHETIC COAL-TAR PRODUCT MADE FROM CHEMICALLY PURE MATERIALS." [What have the Ammoniated people to say to this?]

"A SYNTHETIC COAL-TAR PRODUCT OF THE AMIDOBENZINE SERIES, CONTAINING NASCENT AMMONIA."

"THESE TWO CHEMICALS [stimulant ammonia of coal-tar origin² and chemically pure phenylacetamide] COMBINE UNDER CERTAIN CONDITIONS SO AS TO OBTAIN A PRODUCT WHICH HE [Dr. Cyrus Edson] NAMED PHENALGIN OR AMMONIATED PHENYLACETAMIDE."³

"PHENALGIN IS A COMPOUND OF PECULIAR CHARACTER WHICH CAN NOT BE EXTEMPORANEOUSLY MADE INTO TABLETS FROM THE POWDERED DRUG, WITHOUT SERIOUSLY CHANGING AND IMPAIRING ITS MEDICINAL QUALITIES."

We believe these quotations are sufficient to show what the Etna Chemical Company has "always said it to be." In going over the literature for several years past we find the above stated in the same, or similar, words in nearly all of it. From the above four statements may be deduced: 1. They have stated that Phenalgine is a synthetic preparation; 2. they have conveyed the impression that Phenalgine is a chemical compound; 3. they have announced repeatedly that it is the "only" preparation of the kind, and 4. they have claimed that Phenalgine is non-toxic.

We believe that these four statements represent in plain English what the above quotations mean. They are all absolutely false. Phenalgine is not a synthetic; it is not a chemical compound; it is not the only ammoniated phenylacetamide, or the only acetanilid mixture containing carbonate of ammonia—and it most positively is toxic.

In one place it is stated that Dr. Cyrus Edson

"EMPLOYED HIS GREAT FACILITIES FOR CHEMICAL RESEARCH AND OPPORTUNITIES FOR CHEMICAL EXPERIMENT FOR THE PURPOSE OF PRODUCING A FORMULA FOR A COMBINATION OF STIMULANT AMMONIA OF COAL-TAR ORIGIN (SIC) AND CHEMICALLY PURE PHENYLACETAMIDE, ALSO A COAL-TAR PRODUCT . . . WHICH HE NAMED PHENALGIN, OR AMMONIATED PHENYLACETAMIDE."

In another place we read that Phenalgine is made

"UNDER THE IMMEDIATE SUPERVISION OF THE ORIGINAL INVENTOR OF AMMONIATED COAL-TAR PRODUCTS."

By comparing this last quotation—which is from a current—1905—advertisement—with the preceding one it will be noticed that we are asked to believe that Phenalgine is made "under the immediate supervision of" Dr. Cyrus Edson—and yet Dr. Cyrus Edson died Dec. 2, 1903. This is equal to Lydia Pinkham's prescribing for the suffering women of America when the dear old soul has been dead for over twenty years.

We have before us a full-page advertisement taken from a recent number of a weekly medical journal, which possibly is meant as an answer to the announcement of the Council on Pharmacy and Chemistry that Phenalgine is a simple acetanilid mixture. The advertisement is divided into two parts; the first part is as follows:

"FACTS ABOUT ACETANILIDUM. (ANCIENT HISTORY.)"

"IT HAS LONG BEEN RECOGNIZED THAT ACETANILIDUM AND MOST OTHER COAL-TAR PRODUCTS ARE APT TO EXERT A DEPRESSING INFLUENCE UPON THE HEART, BUT THERE HAS NEVER BEEN ANY DOUBT ABOUT ITS GREAT VALUE AS A PAIN RELIEVER AND TEMPERATURE REDUCER. ITS THERAPEUTIC VALUE HAS, HOWEVER, BEEN PRACTICALLY NULLIFIED BY THE DANGER OF CYANOSIS AND OTHER EVILS CAUSED BY ITS WELL-KNOWN DEPRESSANT ACTION AND THE DIFFICULTY OF OBTAINING IT IN A PURE STATE. IT BEING KNOWN THAT CERTAIN DELETERIOUS SUBSTANCES ARE OFTEN TO BE FOUND IN COMMERCIAL ACETANILIDUM AND THAT MUCH OF THE INJURIOUS EFFECT ATTRIBUTED TO THIS DRUG IS ENTIRELY TRACEABLE TO THESE IMPURITIES."

The above are also falsehoods. The therapeutic value of acetanilid is not practically nullified . . . by the difficulty of obtaining it in a pure state.⁴ Neither is it true that "much of the injurious effect attributed to this drug is entirely traceable to these impurities." While deleterious substances may be found in commercial acetanilid, they are not found in the substance offered as medicinally pure acetanilid by reputable firms. Pure medicinal acetanilid is a cheap article, costing less than 30 cents a pound, for it is a substance that is easily and cheaply purified. It is a fact that the injurious effects are in the acetanilid itself and not in the impurities it may occasionally contain.

The second half of the advertisement in part is as follows:

"FACTS ABOUT PHENALGIN. (MODERN SCIENCE.)"

"MORE THAN A DECADE AGO THE LATE DR. CYRUS EDSON, THEN HEALTH COMMISSIONER FOR NEW YORK CITY AND NEW YORK STATE, RECOGNIZING THE VALUE OF CHEMICALLY PURE ACETANILIDUM AS A THERAPEUTIC AGENT, IF IT COULD BE DEPRIVED OF ITS DEPRESSANT QUALITY, EMPLOYED HIS GREAT FACILITIES FOR CHEMICAL RESEARCH AND OPPORTUNITIES FOR CHEMICAL EXPERIMENT, FOR THE PURPOSE OF PRODUCING A FORMULA FOR A COMBINATION OF STIMULANT AMMONIA OF COAL-TAR ORIGIN AND CHEMICALLY PURE PHENYLACETAMIDE, ALSO A COAL-TAR PRODUCT. THESE TWO CHEMICALS COMBINE UNDER CERTAIN CONDITIONS SO AS TO OBTAIN A PRODUCT WHICH HE NAMED PHENALGIN OR AMMONIATED PHENYLACETAMIDE."

3. This sentence is not complete, but, of course, this is immaterial. Little things like an incomplete sentence do not count.

1. See THE JOURNAL A. M. A., June 21, 1905, p. 1397.

2. DUNSTON'S DICTIONARY: "Synthetic. 'In chemistry the formation of a more complex body by the union of simpler bodies.' Burdett's Dictionary: 'Synthesis. The artificial building up of a chemical compound by the union of its elements.' 'Fusion' is not mixing."

There is more of the same character. In the first place, we call attention to the fact that "Phenylacetamide" is substituted for "Acetanilidum" when it is to go into Phenalgin. To mystify is one of the "tricks of the trade." Few physicians keep up with chemical terms and, therefore, are not supposed to know that Phenylacetamide is one of the chemical names for Acetanilid.

The reference here to Dr. Cyrus Edison brings up another fact, and that is that the Etna Chemical Company tries to convey the idea that Dr. Edison was the originator of Phenalgin. We have always understood that Dr. Cyrus Edison had something to do with pushing Ammonol and, if we remember rightly, got into some trouble thereby. We do not know the exact facts, but the following letter shows that he had a leaning toward another "ammoniated phenylacetamid." The letter is dated "New York, Oct. 6, 1894," and is addressed to the "Ammonol Chemical Company."

"During the past six or eight months I have used Ammonol extensively in my private practice. I have found it excellent in the treatment of neuralgias and for rheumatism. I have also verified your statement in two cases that were suffering from alcoholism. My experience justifies me in saying that it is the safest and best of the analgesic coal-tar derivatives.

"Very truly yours,

"CYRUS EDISON, M.D."

It may be of interest to know that the principal member of the firm of the Etna Chemical Company was at one time a member of the Ammonol Company, and it is usually understood, we believe, that Phenalgin is practically the same as Ammonol—in fact, the analyses published regarding the two preparations show this to be a fact.

We must make one more quotation:

"IT MAKES LITTLE DIFFERENCE TO A PHYSICIAN WHETHER PHENALGIN IS A MIXTURE OR A COMPOUND OR A SYNTHEM, WITH A NAME THAT WOULD DESTROY THE ONTOGENIC BALANCE OF THE UNIVERSE, PROVIDED IT IS JUST WHAT HE HAS ALWAYS FOUND IT TO BE."

Very complimentary to the intelligence and common sense of physicians, is it not?

Suppose some fellow should get up a scheme to exploit a mixture of quinin and some cheap, harmless drug, say, starch—equal parts of each. Suppose he gives it a fanciful name, puts it on the market at a high price, say \$1.25 an ounce, and announces it as a new synthetic with wonderful therapeutic properties. Suppose that the schemer then adopts the nostrum vendor's methods of fooling physicians into using his product by getting some to give testimonials, others to furnish write-ups, and then subsidizes medical journals through liberal advertising, to print both the testimonials and the writeups. The preparation would, of course, prove to be a good thing if it were used in liberal quantities where quinin would ordinarily be used, and some patients using it would get well even if quinin were not indicated. Then with the psychologic effect of the testimonials, the writeups, and good, strong claims rightly pushed, unthinking physicians would do the rest. And then, after a while, when the schemer had gotten to the point where, each year, he was making a fortune out of his preparation, suppose some "self-appointed chemists" should examine into the preparation and discover that it was nothing but quinin and starch and so announce to the doctors of the country; what would the doctors say? That it makes little difference "provided it is just what he has always found it to be"?

This analogy is not far-fetched, for it is practically what has been done with Phenalgin. One difference is that since quinin costs as much per ounce as acetanilid does per pound, the profits on the acetanilid mixture would be sixteen times greater than that of our imaginary preparation. Another difference is that acetanilid is really a dangerous drug, unless used with care, both in its immediate and in its remote effects; quinin is far less so.

"Little difference" indeed, whether we are being humored or not! Evidently!

In conclusion, we charge the Etna Chemical Company with in-

tentionally misleading and deceiving the members of the medical profession, in that the said company has in its literature and in its advertisements conveyed the impression (whether directly stated or not): First, that its preparation, Phenalgin, is a synthetic compound; second, that Phenalgin requires special skill in its preparation; third, that Phenalgin has therapeutic values which it does not possess, and fourth, that Phenalgin is non-toxic.

We also charge that on account of these and other misrepresentations this company has inveigled physicians into prescribing and using a simple mechanical mixture of common well-known cheap drugs—for which an extravagantly high price is charged—under the supposition that this combination of cheap drugs is a chemical compound of special and peculiar merit as a therapeutic agent and, therefore, worthy of their confidence.

Our object in again giving space to this preparation—and practically all we have said applies to the other acetanilid mixtures that are exploited under fictitious names or as chemical compounds (such as ammonol, antikamnia and salacatin or sal-coleoid-Bell)—is to impress on physicians, by a typical example, the shamefulness of the deceptions practiced on them by nostrum manufacturers to the great injury of the public and of the medical profession.

A Protest Against Acetanilid.

Dr. A. Jacobi, in an article on the treatment of tuberculosis (*American Medicine*, Dec. 23, 1905), says:

"I use no acetanilid. I have almost despaired of the effect of my frequently repeated warning against acetanilid, the so-called anti-febrin. Of all the preparations on the market, this cruel antipain poison is the worst. The western firm which disseminates that curse over the country, and that part of the profession which allows itself to be entangled in the complexity of prescribing it on its own blanks over its own names for their unsuspecting and confiding patients, stand guilty of malfeasance and malpractice. One of the greatest shocks to my feelings as a man and physician has been the discovery that our new Pharmacopœia, which should be the pharmacist gospel of both druggists and doctors, participates in the mistake of recommending it. In that Pharmacopœia, p. 3, you find acetanilid; and p. 268, pulvis acetanilid compositus—a mixture of acetanilid, caffeine, and sodium bicarbonate. You recognize the dangerous stuff. It goes by the name of headache powders or by some exotic alluring name. Your Pharmacopœia recommends doses of 0.48 gm. (7.5 grs.), more than 0.32 gm. (5 gr.) of which are acetanilid—and does not even say how many doses the victim may take without having to pay his obolus to Sisy. These headache powders were those a young laboring man had taken when he presented himself in semicomatose and cyanosis a few days ago. They are those which their highest authority permits the pharmacists to sell over the counter. Altogether, I need not say, and you know that the tendency of the new Pharmacopœia to adopt the compound names, is an indignity offered to the profession and an encouragement to the nostrum trade.

A Druggist's Opinion of Patent Medicines.

A well known and highly respected druggist doing a large business in the south part of Minneapolis, puts the following "sticker" on every package sent out from his store:

"It is always wise to consult your family physician.

Avoid patent medicines and fakers.

"40 YEARS' EXPERIENCE."

That is manly and courageous, and as there is no "patent" on the "sticker," we commend it to all druggists seeking the patronage of physicians and the respect of the public and of themselves.—*Northern Lancet*.

We Always Did Like This Story.

Diogenes, lantern in hand, entered the village drug store. "Say, have you anything that will cure a cold?" he asked. "No, sir; I have not," answered the pill compiler. "Give me your hand!" exclaimed Diogenes, dropping his lantern. "I have at last found an honest man!"—(Source unknown.)

To Supervise Nostrums in British Columbia.

The *British and Colonial Druggist* states that the provincial government has appointed a commission to investigate the sale of patent medicines containing harmful ingredients, with a view to legislation to protect consumers against the evil consequences of using these remedies. The step is the outcome of the recent death of an infant, which was poisoned by Luda num contained in a patent medicine.

Correspondence

Oregon and Organization.

PORTLAND, OREGON, Dec. 29, 1905.

To the Editor:—In your issue of Dec. 9, 1905, appears an article by J. N. McCormack, M.D., which, among other unwarranted statements about the medical profession in Oregon, contains this: "There was evidence on every hand that the schools of Oregon do not have high standards of requirements." In commenting on this article editorially, you write: "The average of the profession is low and the medical schools are weak."

By a strange coincidence, THE JOURNAL for December 9, containing these slurs, did not reach me in my mail, so I did not see it until a few days ago, when a copy was handed to me by a medical friend; otherwise I would have replied sooner.

As there are but two medical schools in Oregon, and the medical department of the University of Oregon is one of them, it is fair to assume that that school was included in the general libel on Oregon schools.

As dean of that school since its organization, almost twenty years ago, permit me to say that the statements regarding it made by Dr. McCormack are unjust and without proper foundation.

When the school was organized in 1887, it was what nearly all medical schools in the United States were at that time, a two-year course school. Shortly after that it became a three-year-course school, and in 1895 adopted the four-year graded course requirement. It has always kept at least abreast of the requirements laid down from time to time by the Association of American Medical Colleges (of which it has been a member since 1896), and at present requires four courses of lectures of seven and a half months each, with a curriculum in excess of that required by the Association of American Medical Colleges. Its laboratory and clinical facilities are ample, its lecture corps is efficient, its examinations are rigid. Its students who have gone elsewhere have stood high in other colleges. Its alumni furnish successful, prominent and respected practitioners in all parts of this country. The men connected with the school have labored honestly, assiduously and untiringly, in competition with the large and strongly endowed schools and with much self-sacrifice, constantly to elevate its standard, and they have been successful in keeping it on a plane commensurate with the advanced ideas of the times. Not a year has passed that its efficiency has not been increased.

The school does not pretend to approach in equipment the great endowed medical schools where the attendance is so much greater and where specialties are thoroughly taught, but it does maintain an equipment equal to the needs of the numbers in its classes, and its facilities enable us to teach well and thoroughly. It presents an instance of the small unendowed school doing honest, faithful and efficient work, notwithstanding that it is overshadowed and belittled by its great and haughty brother, the endowed school. But the small school has its work to do, and always will have; further, you will find that the small colleges of the country have given as many or more good men to the world as have the great schools. As in all schools, great or small, some poor students gain entrance and even graduate, so exceptionally such cases may have occurred here; but even if so, no fair minded man would think of making such rarely exceptional cases the standard of worth of the school.

I am surprised that a man occupying the position of chairman of the committee on organization of the American Medical Association should have such a poor conception of justice and equitable rights as to pronounce such judgment as is contained in his screed on Oregon without proper investigation. If his pronouncements on other matters are based on such partial observations and investigations as in the case in point, they are absolutely without value.

Dr. McCormack has done us the gross injustice of publishing to the world, on insufficient and *ex parte* testimony given by prejudiced persons, his conclusions that the schools of Oregon do not have high standards of requirements. Editorially you add insult to injury by stating that this school (it being in-

cluded in the "schools of Oregon") is weak. Evidently Dr. McCormack's mind was poisoned from the lips of those who are jealous of the school and its success, and who vindictively take every opportunity to smirch its good name. Such are to be found in every community which is striving to be or has become a medical center. What was Dr. McCormack's duty before publishing his conclusions regarding this school? Clearly to hear both sides of the question. Had he come to me or to any other member of this faculty for information, it would have been furnished to him gladly. The same remark applies to your own editorial expression. That a great journal should condemn this school as a weakling, on the mere *ipse dixit* of a traveler on organization of the American Medical Association, without notice or opportunity to be heard, is astounding, nay, outrageous.

I met and talked with Dr. McCormack on the evening of his visit and address to the Portland City and County Medical Society, but to me he said never a word about investigating medical schools or reporting on them, nor of wishing information as to what he had heard of them or of their operations.

His strictures on the medical profession of Oregon, and of Portland in particular, founded on half-truths and distorted facts, are unjust and unwarranted, because he has founded a judgment on hasty and superficial investigation of conditions, instead of searching deeply for the whole truth. If he had probed deeper he would have found that those whom he tries to scourge with his rod are the ones who, by effort and loyalty to the medical profession and to the American Medical Association, have been earnest laborers in the work of organization.

S. E. JOSEPHI, M.D.

The above letter was referred to Dr. McCormack, who replies as follows:

BOWLING GREEN, KY., Jan. 7, 1906.

To the Editor:—For nearly five years I have been engaged in a critical study of professional conditions, customs and prospects in nearly every section of the country, and in reporting the results of such observations in a manner intended to be both kind and helpful after my visit to each state. Charged with important duties, I have been forced to say unpalatable things, but, being without either the motive or inclination to do any section or individual injustice, and my work being entirely in the interest of harmony and well-being of the profession of the state or locality visited, Dr. Josephi is the only one who has ever questioned the accuracy of any statement made by me.

I have had numbers of letters from the leading physicians of Oregon expressing regret for the necessity of saying these plain things, but cordially indorsing what I had written, as well as the spirit in which it was done. Without further reference to these, or to the fact that my criticisms were based on personal observation and inquiry in almost every section of the state, I am going to put Dr. Josephi on the stand and prove by him that I might have said much more along the same lines and still be well within the bounds of truth. I said that the schools of Oregon did not have high standards of requirements, and the editorial comment was that they were weak. I quote Dr. Josephi on the same point, so far as his school is concerned: "The school does not pretend to approach in equipment the great endowed schools where the attendance is so much greater and where specialties are thoroughly taught," and, to my surprise, he evinces the unfortunate spirit found so abundantly there, which I had been informed he did not possess, when he says again, "notwithstanding that it is overshadowed and belittled by its great and haughty brother, the endowed school."

I said again, in substance, that personal and factional jealousy dominated the profession of his city. Dr. Josephi makes this appear very mild when he says, in the light of his long experience as a practitioner and teacher there, "Evidently Dr. McCormack's mind was poisoned from the lips of those who are jealous of the school and its success, and who vindictively take every opportunity to besmirch its good name." I submit that neither my article nor the editorial complained of contain anything, in substance or spirit, so conclusive as these quotations.

I am doing this work very reluctantly, and would not do it at all if I could not discuss the results of my investigations with the utmost frankness. The fundamental evils which

form the basis of my criticism were freely admitted to exist in my presence by leaders of the profession, publicly and privately, and knowledge of them is common property in Oregon. I was informed that Dr. Josephi was fitted by both temperament and training to lead in such a movement as would raise the schools, societies and profession above just criticism, and I trust that he will do so. When he reads my article again, after he is restored to his natural good temper, he will find that every line breathes the spirit of kindness, and that every unpalatable truth is told with regret. I quote my concluding paragraph: "My personal experience in Oregon was most pleasant. . . . If a profession with such leaders could only be unified, everything would be possible to it, and it is the hope of arousing them to this duty that I have hesitatingly and reluctantly expressed these criticisms."

J. N. McCORMACK, M.D.

Teaching Nursing by Correspondence.

TOLEDO, OHIO, JAN. 3, 1906.

To the Editor:—The committee on public health and legislation of the Academy of Medicine of Toledo ask for information based on experience which any of your readers may have as to the advisability of teaching nursing by correspondence courses. We wish especially to procure actual experiences which physicians may have had with such nurses. We do not care for arguments as to the logical possibility of such course, but whether in actual practice such nurses are satisfactory, and we wish replies from those who have tried them. These replies will be considered confidential if the writer requests it.

The replies may be sent to the undersigned, the secretary of the society.

WALTER H. SNYDER, M.D.

211 Ontario Street.

Association News

NEW MEMBERS.

List of new members of the American Medical Association for the month of December, 1905:

ARIZONA.

Slayton, F. H., Clifton.

Gideon M. Freeman, M.D., Seattle, Wash., to Miss Violet Lang of Walla Walla, Wash., December 26.

Albert R. Ritchie, M.D., Dunkerton, Iowa, to Miss Dolora E. Everett of Iowa City, Iowa, December 24.

Frank A. Swezey, M.D., Wakonda, S. D., to Miss Antonia Huelman of Sioux City, Iowa, December 25.

Harold N. Simpson, M.D., Harbor Beach, Mich., to Miss Mildred Lane of Ann Arbor, Mich., December 27.

Cornelius A. Frame, M.D., Cambridge, Ohio, to Miss Helen Mae Espie of Caledonia, N. Y., December 27.

W. Edgar Shallenberger, M.D., Chicago, to Miss Elizabeth McIntyre, at Bloomington, Ill., December 21.

Lewis Cass Schutt, M.D., Toledo, Ohio, to Miss Elizabeth Bennett Bailey of Detroit, Mich., December 19.

Clarence A. Revyle, M.D., Lutesville, Mo., to Miss Althea Kalmeyer, at New Florence, Mo., December 23.

Ross McCree Chapman, M.D., Watertown, N. Y., to Miss Harriet Cornell of Ann Arbor, Mich., January 2.

Jacob Winslow Longfellow, M.D., Machias, Maine, to Miss Agnes A. Weingartner of Philadelphia, January 1.

Jacob S. Shoemaker, M.D., New Lothrop, Mich., to Miss Helena Mae Speer of Corunna, Mich., December 20.

Frederick Hazelwood, M.D., Parkin, Ark., to Miss Antoinette Grace Van Wormer of Vassar, Mich., recently.

Floyd Palmer, M.D., Fishkill-on-Hudson, N. Y., to Miss Mary Louise Newman of Anemia, N. Y., December 20.

James W. Richards, M.D., Mechanicsville, Iowa, to Miss Julia Maye Brainard of Wyoming, Iowa, December 27.

Thomas K. Slaughter, M.D., Belleview, Fla., to Miss Eunice Newton of Guthrie, Ky., at Sutherland, Fla., December 23.

Marriages

William E. Hastings, M.D., Mount Vernon, Ind., recently.
 Lloyd H. Fick, M.D., to Miss Ida Boyer, both of Reading, Pa., December 28.

Charles M. Alt, M.D., Baltimore, Ohio, to Miss Minnie De Vaux, December 23.

Francis F. Johnson, M.D., to Mrs. Ada Bradley, both of San Francisco, December 10.

John Adams Miskys, M.D., to Miss Esther Allen, both of Philadelphia, January 2.

G. B. Fetter, M.D., to Miss Helen B. Stitzel, both of Londonville, Ohio, December 27.

William W. Durbin, M.D., to Miss Daisy Sherrill of Columbus, Miss., December 27.

Richard Lightner Sutton, assistant surgeon U. S. Navy (retired), to Miss Magdalena Igel, at Leavenworth, Kan., January 3.

Deaths

August F. Lemke, M.D. Medical Department of the University of Illinois, Chicago, 1895, of Chicago, a member of the American Medical Association, Illinois State Medical Society, Illinois Association of Military Surgeons, Chicago Medical Society, Chicago Pathological Society and other scientific organizations; interne in Cook County Hospital in 1895-1896; pathologist to the Illinois Eastern Hospital for the Insane Hospital until 1898; assistant surgeon of the Third Illinois Infantry, U. S. V., in the Spanish-American War; and afterward captain and assistant surgeon Ill. N. G., assigned to Third Infantry; associate professor of medicine in the College of Physicians and Surgeons, Chicago; at times on the staff of Cook County Hospital, Mercy Hospital and other institutions, a pathologist of great promise, who was obliged to leave Chicago on account of ill health in October, 1904, died at his home in Pasadena, Cal., January 6, from sarcoma of the face and neck, aged 32.

Lehman H. Dunning, M.D. Rush Medical College, Chicago.

1872; member of the American Medical Association and chairman of the Section on Obstetrics and Diseases of Women in 1904; member of the Indiana State Medical Society, and president of the Marion County Medical Society; member of the American Association of Obstetricians and Gynecologists; delegate to the Ninth International Medical Congress; professor of diseases of women in the Medical College of Indiana; consulting surgeon to the Indianapolis City Hospital and City Dispensary; chief of staff of and gynecologist to the Deaconess Hospital, Indianapolis, died at his home in that city, January 4, from heart disease, at the age of 55.

Robert Bruce Stover, M.D. Jefferson Medical College, Philadelphia, 1858, of Richmond, Va., died December 31, in Williamsburg, Va. He served two years as assistant surgeon in the Confederate service. In 1879 he went through a severe epidemic of yellow fever in Memphis. In 1883 he moved to Richmond and established himself in practice, where he lived up to a few months of his death. He was associate editor of the *Atlantic Journal of Medicine*, surgeon to Lee Camp, Confederate Veterans, and to the Confederate Soldiers' Home.

Thomas Y. Aby, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1866; for several years assistant quarantine officer of Louisiana at Quarantine, at the mouth of the Mississippi; assistant surgeon of the Washington Artillery in the Confederate service during the Civil War; acting assistant surgeon, U. S. Army, in the Spanish-American War, and on duty with the Twentieth Infantry at Santiago; twice state senator, died at his home in New Orleans, December 24, from cerebral hemorrhage, after an illness of a year, aged 65.

Orlando Sampson Strange, M.D. New York University, New York City, 1849; member of the College of Physicians and Surgeons of Ontario, 1866; licentiate of the Medical Board of Upper Canada, 1850; mayor of Kingston in 1859 and 1860; alderman for several years; a member of the Ontario Medical Council from 1872 to 1875; surgeon at the penitentiary for 11 years, died at his home in Kingston, Ont., January 2, after a long illness, aged 80.

Thomas Warfield Simmons, M.D. Jefferson Medical College, Philadelphia, 1861; a member of the Medical and Chirurgical Faculty of Maryland; president of the Washington County Medical Society in 1894; county physician from 1892 to 1896; health officer of Hagerstown for several years, died December 30 from uremia two days after an operation for intestinal obstruction, at the Washington County Hospital, Hagerstown, aged 69.

James Frazier Davis, M.D. Hospital College of Medicine, Louisville, Ky., 1880, formerly of Louisville, was found dead, December 24, in Long Lick Creek, near his home in Bardstown

Junction, Ky., aged 51. It is supposed that his horse walked over a bluff, dragging the buggy, and that the fatal injuries were received as a result of the fall, as the creek at the point where the body was found was only 18 inches deep.

William R. Blue, M.D. University of Louisville Medical Department, 1888; a member of the American Medical Association; for several years professor of genitourinary and skin diseases in the Hospital College of Medicine, Louisville; a prominent specialist in these departments in Louisville, died at the home of his sister in Rome, Ga., January 1, from paralysis, after an illness of a year, aged 40.

John C. Campbell, M.D. University of the State of Missouri Medical School, Columbia, 1874; a practitioner for 65 years; formerly of Nebraska City, Neb.; sometime member of the territorial legislature, of the territorial council and of the state constitutional convention; for six years a member of the board of education, died at the home of his daughter in Asheville, N. C., December 12, aged 90.

John Hodges Drake, M.D. Medical College of Alabama, Mobile, 1891; formerly of Opelika, Ala., but for six years past, on account of lung disease, a resident of Asheville, N. C.; a member of the American Medical Association; and a specialist in diseases of the eye, ear, nose and throat, died at his home in Asheville, December 13, from pneumonia, after an illness of a few days, aged 36.

Christopher C. Clements, M.D. Jefferson Medical College, Philadelphia, 1864; captain and later brigade surgeon during the Civil War; sometime president of the Greene County (Mo.) Medical Society; president of the Springfield Board of Health, and member of the city council, died at his home in Springfield, December 20, after a long illness, aged 67.

George H. Granger, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1867; a veteran of the Civil War; representative in the Michigan legislature from 1879 to 1882; president of the Bay City board of education for three terms, died at his home in Bay City, December 22, from diabetes, after a lingering illness, aged 64.

George F. Chalmers, M.D. Cooper Medical College, San Francisco, 1894, of Niles, Cal.; health officer of that place for seven years; district surgeon for the Southern Pacific System, and temporary superintendent of the Masonic Home, Decoto, died at the Railroad Hospital, San Francisco, December 26, four days after an operation for appendicitis, aged 37.

Silas Proctor Ems, M.D. University of the Victoria College, Coburg, Ont., 1862; member of the College of Physicians and Surgeons of Ontario, 1866; sometime coroner of Welland County, died at his home in Niagara Falls, Ont., from nephritis, December 26, aged 67.

Thomas P. Coleman, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1859; one of the oldest practitioners of Northern Mississippi, died at his home in Oxford, December 27, from injuries received in a railway accident five days before.

Francis Duncan, M.D. Rush Medical College, Chicago, 1900, a member of the American Medical Association and a promising young physician of Chicago, died suddenly from heart disease at San Diego, Cal., January 2, aged 30. He had been married only ten days before.

Joseph Carbert, M.D. University of the Victoria College, Coburg, Ont., 1856; licentiate of the Medical Board of Upper Canada, 1852; member of the College of Physicians and Surgeons of Ontario, 1886, died at his residence in Toronto, Ontario, January 2, aged 79.

Thomas Garth, M.D. Cincinnati, 1864; a veteran of the Civil War; justice of the peace for eight years; coroner of Wright County, Iowa, for 16 years; mayor of Clarion, Iowa, for one term, died from abscess of the liver at his home in Clarion, December 19, aged 70.

Walter R. Francis, M.D. University of Buffalo Medical Department, 1876, of Marion, Ind.; a member of the Grant County Medical Society; once health officer of Grant County, died from paralysis at the home of his son in Buffalo, N. Y., December 28, aged 52.

Theodore Edward Beard, Jr., M.D. Yale University Medical Department, New Haven, Conn., 1897, a member of the American Medical Association and of the Connecticut Medical Society, died at his home in New Haven, January 1, aged 41.

Julius Alexander Caldwell, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1854, a prominent practitioner of Salisbury, N. C., died suddenly at his home in that city, from heart disease, December 21, aged 75.

George W. Corbett, M.D. College of Physicians and Surgeons of Chicago, 1901, died at his home in Plymouth, Wis., December 16, about one day after a runaway accident in which he sustained a severe concussion of the brain, aged 38.

Robert Mitchell, M.D. University of Edinburgh, Scotland, 1839, L.R.C.S., Edinburgh, 1859; for 21 years surgeon to the Dorchester (N. H.) penitentiary, died at his home in Andover, N. H., December 27, after a brief illness, aged 73.

Arthur Guy Beazley, M.D. Atlanta (Ga.) Medical College, 1866, private and later assistant surgeon in the Confederate service during the Civil War, died at his home in Crawfordville, Ga., December 25, after a long illness, aged 69.

John Henry McFaul, M.D., C.M. University of Trinity College, Toronto, member of the College of Physicians and Surgeons, Ontario, 1888, died suddenly from angina pectoris at his home in Toronto, Ont., December 23, aged 62.

J. A. Sabourin, M.D. Laval University Medical Department, Quebec, 1902, of Point St. Charles, P. Q., died at the Hôtel Dieu, Montreal, December 28, from typhoid fever, after an illness of three weeks, aged 30.

Theophilus Grenier, M.D. Laval University Medical Department, Quebec, P. Q., 1879, health officer of Newton Township, Mackinac County, Mich., died at his home in Gould City, Mich., December 20, aged 54.

D. H. Brewer, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1886, died at his home in Brenham, Texas, December 19, after an illness of nearly four years, from tuberculosis, aged 45.

John R. Atkinson, M.D. University of Nashville Medical Department, 1869, a Confederate veteran, died at his home in Lavinia, Tenn., December 29, from tuberculosis, after a long illness, aged 65.

Thomas A. Brown, M.D. Jefferson Medical College, Philadelphia, 1873, for several years a practitioner of Wilmington, Del., died on his farm near Frederica, Del., December 28, after a long illness, aged 57.

George W. Duane, M.D. Harvard University Medical School, Boston, 1844, for more than 60 years a practitioner of Barnstable County, Mass., died at his home in Hyannis, December 29, aged 81.

Hilary D. Bruce, M.D. Atlanta (Ga.) Medical College, 1882, a practitioner for 45 years, died suddenly at his home in Waverly, Ala., December 17, from heart disease, aged 74.

Travis L. Cooper, M.D. Memphis Hospital Medical College, 1902, died at his home in Calogee, Miss., December 26, from tuberculosis, after an illness of two years.

Daniel Booher, M.D. Medical College of Ohio, Cincinnati, 1894, died from tuberculosis at his home in Elizabeth, Colo., December 20, after an illness of four years.

Rollin B. Carter, M.D. Ohio, 1881, of Akron, Ohio, died at a sanitarium in Cleveland, December 23, from sciatica, after a long illness, aged 47.

John J. Cronin, M.D. College of Physicians and Surgeons in the City of New York, 1893, died at his home in New York City, December 3.

DeForrest W. Chase, M.D. Medical School of Maine of Bowdoin College, Brunswick, 1889, died at his home in Boston, December 19.

David R. Davis, M.D. University of Pennsylvania Department of Medicine, 1893, died at his home in Lansford, Pa., January 5.

Charles E. Wentz, M.D. Medical College, Philadelphia, died at his home at New Providence, Pa., January 3, aged 28.

W. T. Roney, M.D. Medical College of Georgia, Augusta, 1891, died December 16, at his home in Spread, Ga.

George L. Buck, M.D. Marion, Ind., 1889, died at his home in Star City, Ind., December 11, after a long illness, aged 52.

Miscellany

Deaths in India from Wild Animals. Over 2,000 deaths directly attributable to wild animals have occurred in India in one year. In addition, 21,880 deaths were entered as caused by snake bites. The official figures show that 88,206 cattle were destroyed by wild animals, 10,756 by snakes. While the government of India makes strenuous efforts to reduce the mortality due to wild animals, only 16,122 were killed in the year.

The people of India apparently make little effort to better this condition (owing to religious scruples).—*Medical Age*.

Arsenic in Animals.—An address was read by the Prince of Monaco before a recent meeting of the Paris Société de l'Internat, describing some of the results of his voyages to Arctic regions and other remote parts of the oceans. Arsenic was detected in fish from depths of nine to twelve thousand feet, and also in fish and animals in the Arctic regions, and in animals at altitudes of six thousand feet and more on lonely islands in unrequented seas. The speaker referred also to scientific findings registered by instruments sent up on kites or balloons from his vessel in ocean wilds. They rose to an altitude of 16,300 meters or nearly 10 miles. He usually has several scientists as guests on his vessel, the *Princess Alice*, which is lavishly equipped for scientific research. His "ocean museum" is one of the sights of the Riviera.

Paget's Disease of the Bones.—Menetrier and Rubens-Duval report (*Bull. et Mem. de la Soc. Méd. des Hôpitaux*, June 1) a case of Paget's disease of the bones treated with antisyphilitic remedies with success, an arrest of the process being produced. This case confirms the view expressed by M. M. Lannelongue and Fournier as to the hereditary syphilitic nature of the disorder, but seems to prove that acquired syphilis may also be its cause. They refer to another similar case reported by Gaucher in which Paget's disease was materially benefited by hypodermic injections of benzoate of mercury, and still another one reported by Frechon (*Thèse de Paris*, 1903). They conclude that Paget's disease is not only dependent on syphilis, but that its lesions themselves are syphilitic.

Tuberculous Meningitis.—Claisse and Abrami (*Bull. et Mem. Soc. Médicale des Hôpitaux*, May 18), report a case of tuberculous meningitis, verified by inoculation experiments, as well as clinically, terminating in apparent perfect recovery. They consider, therefore, that the absolutely fatal prognosis of this disease must be somewhat modified. At the following seance of the society M. M. Vaquez et Digne reported another case which, if not cured, was very greatly improved and the patient returned to his work. The inoculation, with liquid from lumbar puncture, experiments on a guinea-pig in the earlier course of the disease produced numerous tuberculous lesions and demonstrated bacilli. Six weeks later similar inoculations on two guinea-pigs failed to produce any symptoms, thus indicating that the infection was not as virulent at that time as on the former occasion.

In Memory of Carrión, the Peruvian Martyr to Science.—The local medical society of Lima, Peru, always devotes the 5th of October to the memory of Dr. Daniel Carrión. This year was the twentieth anniversary of his death, and the story of his devotion to science was again related. He was convinced that Peruvian verruga and Oroya fever were one and the same disease, although apparently so different in their manifestations. This assumption was confirmed by experiments on animals, but they did not convince the medical world. To decide the matter once for all, he inoculated himself with the virus of the verruga, and as the resulting "Oroya fever" developed he wrote a graphic record of the disease as observed in himself. Schenbe regards the disease as a severe form of yaws, modified perhaps by the high altitude of the regions in South America where only it occurs, and possibly by malaria.

Poisoning by External Application of Resorcinol.—Kaiser (*Therap. Monatsh.*, October, 1905, p. 540), reports a case in which a patient affected with lupus vulgaris was ordered to apply to the back a resorcinol plaster, 600 sq. cm. (about 10 inches square). Two days later an application was made of 100 gm. (about 3 ounces) of a 50 per cent. resorcinol-zinc oxid ointment. Very soon a severe burning pain was produced, with profuse sweating. The application was removed within an hour, by which time the patient was apparently unconscious, but shrieked furiously and had clonic spasms. The pulse and respiration were much accelerated. These conditions lasted ten minutes, when opisthotonos supervened. Spasms and relaxations occurred every twenty or thirty seconds. After the fortieth spasm the patient went into a quiet unconscious state. In about an hour from the beginning of the convulsive state, the pulse and respirations improved, the reflexes reappeared, and consciousness slowly returned. The urine, voided three

and one-half hours after the application of the paste, was greenish and soon became black on exposure to air. Phenol was detected, but no albumin. In a few days the patient apparently had fully recovered.

Arsenic in Diabetes.—H. Verdalle (*Arch. Gén. de Méd.* No. 23, June 6), concludes, from a series of clinical observations which he publishes, that treatment of diabetes by arsenical chlorinated soda water is very effective, most so in the hyperhepatic form described by Gilbert. It affects both the glycosuria and the urea output, the former often disappearing entirely and the latter tending to return to the normal figure. The other elements of the urine are hardly affected. The general condition is markedly and durably improved and sometimes cure is complete. In every form of diabetes this amelioration is pronounced, and in no case did he observe any accidents imputable to the treatments.

Poisoning by Atoxyl (Arseno-anilid).—Bornemann (*Munch. med. Wochsft.*, No. 22, p. 1043), reports the case of a patient suffering from a widely-diffused lichen ruber planus, who was treated by local application of a tar-sulphur ointment and injection of a 20 per cent. solution of atoxyl, beginning with 0.5 c.c. (7.5 minims) and increasing to 2 c.c. (30 minims). The injections were repeated three times a week. The first symptoms appeared after the treatment had continued for two months. They were debility, cardiac weakness, dryness of the throat and enteritis. The patient interrupted the treatment for a short time and then began to use 1 c.c. (15 minims) of the remedy twice a week. In the course of three weeks the following symptoms were manifested: Partial deafness, buzzing noises, burning sensation in the feet at night, mist before the eyes, diminished vision and, finally, amaurosis. The dose was increased to 2 c.c. (30 minims) three times a week, when swelling of the hands, feet and face occurred. After a total of 27 grams of atoxyl had been taken in the course of three months the patient was removed to a hospital and the drug entirely suspended. By the application of zinc ointment the edema was reduced, and the original affection (lichen) cured by the employment of salicylated vaselin, chrysarobin, carbolsulphinate and, finally, by the use of x-rays. The amaurosis remained. The ophthalmoscope showed atrophy of the optic nerve. A sensation-to light was all that could be perceived, but the pupils reacted well.

Official Medical Fees in Case of Industrial Accidents in France.—*The Presse Médicale* of October 25 gives the full text of the new decree regulating the fees for medical attendance for workmen injured while at work. The patient is allowed to choose his own physician and druggist, but the proprietor of the industrial establishment is not held responsible for a sum above the fees officially established. These fees are 40 cents (2 francs) for each visit to the house when the patient is unable to come to the doctor's office or it is inconvenient for any reason. This fee is increased to 50 cents at places where the usual fee was this amount or more before 1901; in small places of less than 5,000 inhabitants it is reduced to 30 cents. This fee is reduced by 10 cents when the patient goes to the doctor's office. It includes the price of a simple dressing or aseptic bandage. The fee is doubled when the doctor's visit has to be made at a specified hour, and tripled when it is required between 9 p. m. and 6 a. m. When the visit has to be followed by prolonged oversight in the eventuality of complications threatening life, each additional half-hour, to a maximum of five, is counted as a separate visit. Mileage is also allowed the physician when the visit has to be made at a specified hour or at a place where the physician has no regular office, the amount ranging from 20 centimes per kilometer by railroad to 40 centimes by other conveyance (this is about 7 to 14 cents a mile). A special fee of 10 cents is allowed for the first medical certificate, or, in case the lesions are multiple, the fee may be \$1. The same amount is allowed, also, for the final descriptive certificate when the patient is dismissed.

The rates for dressings and for minor operations are given as corresponding to the fee for one visit for pulling a tooth, massaging a hand or foot, etc., up to a fee as for ten visits for general anaesthesia, puncturing of cysts, followed or not by injections, reduction of luxations not yielding to gentle measures (wrist, lower jaw and knee), reduction of simple fractures of body of humerus, forearm, radius or clavicle, reduction of simple fracture of the lower jaw, amputation of a finger or toe, and extirpation of a

hematoma, encysted foreign body or small inflamed bursa. The fees for more extensive surgical operations are graduated as follows: For vascular amputation, reduction of fractures of the tibia below; for ligature of the radial, ulnar, facial or temporal artery, the fee is from \$4 to \$7 according to the local rate for visits. For curetting the uterus; tenotomy with suture of the superficial tendons of wrist, ankle, hand or foot; pericardiomyotomy not including the sphincter of the anus; simple trephining of the skull; reduction of fractures of wrist or bones of face in or near a joint, the fee ranges from \$5 to \$8, according to the local rate for visits. The fee for complicated traumatic aneurysm, an aneurysm of the carpus, wrist, ankle, foot, knee or elbow; for ligature of the tibial or peroneal, popliteal, femoral, iliac, carotid, palmar or plantar arteries, and for simple empyema. The fee is \$8, \$11 or \$15, according to the local visit rate, for reduction of the fracture of body of femur or tibia, knee, ankle, patella, spine or pelvis; amputation of the arm; ligature of the subclavian or axillary arteries. The fee is \$12, \$15 or \$20 for uncomplicated tracheotomy or celiotomy; operation on kidney or liver; injury or inflammation of the reduction of fracture of both bones of the leg; arthrodesis of shoulder or hip joint; disarticulation of the foot or ankle, knee or elbow; amputation of the forearm, or leg and for exploratory laparotomy. The fee for disarticulation of the shoulder or fracture of the external iliac is \$15, \$20 or \$26, according to the local visit rate. For disarticulation of the hip or amputation of the thigh the fee is \$22, \$30 or \$40. A sliding scale of fees is also given for certain other operations as follows: curetting and scraping bone, \$5 to \$8; evulsion and trephining bone, \$8 to \$15; cataracts and suturing nerves and tendons aside from those mentioned in the first sections of the decree, \$8 to \$15; retroterine hematocle, \$8 to \$15; reduction of fractures of the skull, \$8 to \$15; reduction of luxations requiring apparatus or force, \$8 to \$15; large abscesses and deep abscesses, \$11 to \$15; empyema requiring resection of ribs, \$11 to \$20; antipathologic operations, \$11 to \$20; reduction of fractures of elbow or forearm, \$11 to \$20; reduction of fractures after rupture of the uterus, \$11 to \$20; articular resections of foot, ankle, knee or elbow, \$15 to \$20; complicated tracheotomy, \$15 to \$25; laparotomy followed by operations on abdominal viscera, \$15 to \$20; tenotomy with complications (artificial anastomosis, etc.), \$15 to \$20; pericardiomyotomy, \$15 to \$20; resection of intestine, etc., \$15 to \$30; resection of the elbow or hip, \$15 to \$30; Eslander operation, \$20 to \$30; complicated quivering force and casts and involving elbow or hip, \$15 to \$30. The fees for specialists are also established as follows: An ophthalmologist's examination and simple dressing, 60c.; removal of foreign body and dressing, \$1; removal of foreign body in cornea, with keratitis and four dressings, \$1; operation of average importance and four dressings, \$7, and serious operations, for traumatic cataract, extraction of foreign body in vitreous, of the lens, emulsification, excision, iridectomy, etc., and four dressings, \$15. Every dressing after the fifth is counted as a maximum of twenty dressings. The fee for examination by an ophthalmologist is \$1, including a simple dressing; thorough examination of cornea, \$2; anterior tamponing of nasal fossa, \$1; antero-posterior tamponing of nasal fossa, \$4; removal of a foreign body in ear, nasal fossa or pharynx, without operation, 50c.; removal of foreign body in larynx, by endotracheal route, \$4; surgical removal of foreign body in ear, nose (by the Rongé or a similar operation), \$12; surgical removal of foreign body in larynx, requiring laryngotomy, tracheotomy or trephining of the mastoid process, \$15.

The account presented by the physician should include the name and address of the physician and also of the patient and of the proprietor of the factory, the date of the accident, a chronologic statement as to all the examinations, certificates, consultations, operations and circumstances which might affect the price, such as night calls, mileage, etc., and the exact denomination of the operations, according to the above tariff, with the sum total of the fees. The medical assistants during a major operation are to be paid at the rate of one-fourth of the fee allowed for the operation, the total thus allowed not to be more than half the fee, no matter how many assistants may have been present. The application of the first dressing or cast is included in the fee. In charging the French franc into dollars and cents, it has been estimated at twenty cents; in reality, it is half a cent less.

Book Notices

METHODS OF ORGANIC ANALYSIS. By H. C. Sherman, Ph.D. (Chap. Pp. 215. Price, \$1.75. New York: The MacMillan Co., 1905.

The fact that the greater part of this book is devoted to quantitative methods for analysis of foods and related substances makes the work especially desirable. These methods have been taken largely from official publications and are, therefore, standard. Because of its small volume the book will be convenient.

MATERIA MEDICA AND PHARMACY. By R. W. Wilcox, M.A., M.D., LL.D. Sixth Edition. Cloth, Pp. 624. Price, \$2.50 net. Philadelphia: P. Blakiston's Son & Co., 1905.

The revision of the United States Pharmacopoeia, with many changes and additions necessitated the rewriting of this book, long so popular as "White and Wilcox," and division of the subject in two parts. There is consequently to be a second

volume to be known as "Pharmacology and Therapeutics." Since matters medicinal are now receiving much attention this well-known work will no doubt be appreciated. Its utility as a text-book, especially owing to its condensed form, has long been recognized.

CLINICAL TREATISES ON THE PATHOLOGY AND THERAPY OF DISORDERS OF METABOLISM AND NUTRITION. By C. von Noorden. Part VII. Translated by P. Buchanan, D.Sc., and L. W. Hall, M.D. Cloth. Pp. 211. Price, \$1.50. New York: E. B. Treat & Co., 1905.

This little book of 210 pages is a most interesting collection and review of recent contributions to our knowledge of this subject. It is also valuable for the commentary of its illustrious author. His own views and the results of studies coming from his laboratory are fully explained, but properly balanced in his exposition of the work of others. The symptoms and course of the disease are not considered in detail. The first 80 pages are devoted to a review of the various theories which have been propounded to account for the disease. This is undoubtedly the most interesting part of the book. The next chapter is on acetone-bodies, their source, grouping, conditions necessary for their appearance, and the dangers of acetonuria. A chapter on other changes in metabolism and three on general course and prognosis follow. The final chapter deals with treatment, and is a clear and full exposition, the author's great experience enabling him to give the details in a practical manner.

PROGRESSIVE MEDICINE. A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by H. A. Hare, M.D., assisted by H. R. M. Landis, M.D., vol. IV, December, 1905. Diseases of the Digestive Tract and Allied Organs: Liver, Pancreas and Peritoneum—Anesthetics, Fractures, Dislocations, Amputations, Surgery of the Extremities and Orthopedics—Genito-Urinary Diseases—Diseases of the Kidneys—Practical Therapeutic Refereudum. Paper. Pp. 327. Price, \$6.00 per annum. Philadelphia: Lea Brothers & Co., 1905.

The excellency of this volume is in keeping with those previously issued. It is written by thoroughly qualified men who have the requisite clinical experience to enable them to take from the literature all there is of practical value and present in a readily accessible and interesting manner. Dr. J. Dutton Steele writes on the diseases of the digestive tract and peritoneum; Dr. W. T. Belfeld discusses genitourinary diseases; Dr. J. R. Bradford writes on the diseases of the kidneys, and Dr. J. C. Bloodgood discusses anesthetics, fractures, dislocations, amputations, surgery of the extremities and orthopedics. Under the title Practical Therapeutic Refereudum, Dr. H. R. M. Landis writes on new remedies and agents used for medicinal purposes.

Queries and Minor Notes

RECIPROCITY.

To the Editor: 1. Does Georgia accept a Pennsylvania state license without further examination? 2. Whom shall I address regarding registration in Georgia? **INSURER.**

ANSWER. Regarding both matters write to Dr. E. R. Anthony, Griffin, Ga.

State Boards of Registration

COMING EXAMINATIONS.

ILLINOIS State Board of Health, Great Northern Hotel, Chicago, January 18-20. Secretary, J. A. Egan, Springfield.

NEW YORK State Board of Medical Examiners, Albany, January 20-February 2. Secretary, Charles P. Wheelock, Albany.

NEBRASKA State Board of Health, State House, Lincoln, February 7-8. Secretary, George H. Brash, Beatrice.

Rules Governing Reciprocity Between New York and New Jersey.

In accordance with the resolution passed at the conference held Oct. 16, 1905, between the educational and medical representatives of the states of New York and New Jersey, the committee appointed for the purpose met Nov. 11, 1905, and formulated the following rules and regulations to govern reciprocity in medical licensure between the states mentioned, on and after Jan. 1, 1906:

The basis on which reciprocity shall obtain between the states of New Jersey and New York shall be a license earned on examination in either one of the states.

2. A candidate for indorsement of a medical license must present credentials from the officials of the state board of medical examiners which licensed him showing that at the time of such application for indorsement he is a reputable practitioner of medicine and in good standing in the profession and in the community.

3. When an applicant presents his papers for indorsement to the board of one state and this board has reasonable doubts of the qualifications of the applicant, either personal or professional, said board shall return the certificate of indorsement, together with its reasons, to the board which issued it and ask for a reconsideration of the certification. Where an applicant presents a license issued prior to the establishment of reciprocity, the board to which the application is made may require for its consideration the original papers on which the license was granted, or a certified copy thereof. The original state license only can be indorsed by either board. No application for indorsement of other indorsements will be considered.

4. No person who has been rejected for license by the New York or the New Jersey board shall be privileged to have a license indorsed by either state unless a period of at least six months shall have elapsed since such rejection occurred. Candidates licensed by the New Jersey State Board of Medical Examiners in the years 1904 and 1905 must have five years of suitable practice subsequent to the earning of their medical degree, before obtaining a consideration of their request by the New York authorities for the indorsement of their New Jersey licenses. This shall not apply to New Jersey graduates of the classes mentioned who fully meet the requirements exacted by the New York State medical laws at that time.

5. The preliminary education required for admission to medical schools shall be the same for both states and the certification of the education department of either state to the standards maintained by secondary schools or high schools in either state shall be accepted by the education department of the other state. The standards to be required of secondary schools and academies without the states of New York and New Jersey shall be fully equivalent to those required of the schools within those states and the schools to be registered as maintaining such equivalent standards shall be determined in joint conference between the educational departments of New York and New Jersey.

6. The recognized medical schools registered as maintaining the required standard shall be those on the "approved list" of the education department of the state of New York.

7. The full and entire list shall be given by the board of each state to the examinations held by the board of the other state.

The committee also recommended that efforts be made to amend the laws of one or both states to annul a number of minor differences which at present in some instances render reciprocity difficult.

California Revocations.—The State Board of Medical Examiners recently revoked the licenses of O. C. Josselyn, H. McGregor Wilson, and L. H. Meadows (alias Weston), who were convicted in the United States District Court of sending matter regarding criminal malpractice through the mails.

Illinois October Report.—Dr. J. A. Egan, secretary of the Illinois State Board of Health, reports the written examination held at Chicago, Oct. 18-20, 1905. The number of subjects examined in was 16; total number of questions asked, 160; percentage required to pass, 75. The total number of candidates examined was 61, of whom 52 passed and 6 failed, including 2 not rated and 1 who withdrew. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Chicago Homeo. Med. Coll.	(1890)	76	
College of P. and S., Chicago	(1904) 83.6;	(1905) 80.4,	85.6
George Washington University	(1905)	88.3	
Hahnemann Med. Coll., Chicago	(1888)	75

Missouri.—At the examination held by the State Board of Health at Kansas City, Dec. 19-21, 1905, the following questions were asked:

ANATOMY.

1. Describe the stomach. 2. Describe the liver. 3. Describe the pancreas. 4. Name the so-called ductless glands. 5. Describe the spleen. 6. Describe the thyroid gland. 7. What is the abdominal cavity? 8. Name the organs of the abdomen. 9. Name the regions of the abdomen. 10. What parts are included in each region?

PHYSIOLOGY.

1. What is the function of the cerebellum? 2. How many refracting surfaces does a ray of light pass through on its way to the retina? What are they? 3. What is the office of the spleen? 4. Give steps in digestion of proteins. 5. Give fetal circulation.

CHEMISTRY.

1. What is a molecule? 2. What is an element, and how many are there? Give illustration. 3. What would be antitoxins for arsenical and strychnin poisoning? 4. Give difference between chronic and acute form of lead poisoning. What are the sources of each? 5. Give (chemically) steps in manufacture of alcohol. 6. Give chemistry of respiration. 7. What is the chemical composition of milk? 8. Give antidotes for phosphorus; also treatment for phosphorus poisoning. 9. Give properties of hydrogen gas. 10. What are the constituents of urine? Give normal specific gravity.

BACTERIOLOGY.

1. Describe *Bacillus pseudotuberculosis*. 2. Give description of Lankaster's bacillus. 3. Differentiate (bacteriologically) between diphtheria and follicular tonsillitis. 4. What is the method ordinarily used in detecting gonococci? Also culture characteristics. 5. What is a mixed infection? Give example.

PATHOLOGY.

1. Give the structural changes that occur in tuberculous joints. 2. Describe the blood changes in pernicious anemia. 3. Give the pathology of the second and third stages of lobar pneumonia. 4. Discuss cheesy degeneration. 5. Discuss metastatic abscess formation.

MEDICAL PRACTICE.

1. Locate the (normal) apex beat of the heart. 2. What conditions increase the area of heart dullness? 3. Describe and locate the pain in (a) appendicitis, (b) renal calculus, (c) gallstones. 4. Give some of the chief characteristics that differentiate an acute from a chronic form of disease. 5. What is collapse? Mention two frequent conditions in typhoid fever that are attended with collapse and indicate treatment in each instance. 6. Describe (a) an intermittent pulse, (b) an irregular pulse. 7. Give (a) and (b). 8. Give a brief description of each of the following diseases, embracing etiology, symptoms and general management: typhoid fever, tetanus, empyema, cystitis.

SURGERY.

1. Define shock and how should you treat it? 2. How would you treat a fracture of the shaft of the femur? 3. How would you treat a Colles' fracture? Describe fracture and treatment fully. 4. Describe an operation for popliteal aneurism. 5. Give symptoms of stone in the bladder of a male. 6. How would you treat a stone in the bladder of a female? 7. What is the method to adopt to remove a kidney. 8. Name the luxations of the shoulder joint; symptoms of each and how reduced. 9. Describe erysipelas: (a) simple; (b) phlegmonous, and treatment. 10. How would you perform external perineal urethrotomy?

OBSTETRICS.

1. Name all the female reproductive organs. 2. Describe the uterus, and give its nerve and blood supply. 3. Name all the signs of pregnancy at the end of second month. What is Braxton-Hick's sign? 4. Name some of the more important diseases of the fetus in utero. 5. What is ballottement? When is it available and how is it performed? 6. How many vertex presentations can we have? Tell how to make the diagnosis in vertex presentations. 7. What is cephalic version? When is it necessary and how is it performed? 8. What is an impacted breech presentation? Give diagnosis and explain method of delivery. 9. Under what circumstances would you suggest podalic version? How is it performed? 10. Describe in full your management of normal labor; (a) as relates to mother; (b) as relates to child.

GYNECOLOGY.

1. What is subinvolution? Give the results of subinvolution of the uterus. What is its treatment? 2. When is intrauterine irritation justifiable? Describe the technique of its use. 3. When is ventrofixation of the uterus justifiable? Describe the operation. 4. What is endometritis? Give its treatment. 5. Give symptoms and treatment of (a) anemia and give treatment, (b) chlorosis and give treatment.

THERAPEUTICS.

1. What causes autohemolysis? Give treatment. 2. What is nocturnal aurasis? Give treatment. 3. Give physical signs and treatment of pericarditis. 4. Give therapeutics of acetic acid. 5. Define anthrax. Give its etiology and treatment. 6. Define styptics and hemostatics. Mention two of each. 7. Mention the causes of influenza or grip. Give treatment. 8. Give symptoms and treatment of acute pleurisy. 9. Give treatment of a case of renal colic. 10. Give treatment of a case of acute gout.

HYGIENE.

1. What are the elementary principles necessary to man's existence? 2. What is the physiologic effect of alcohol (a) on the nerve centers; (b) on the muscular system; (c) on the skeleton? 3. Differentiate between the physical and chemical condition of soil? 4. What is the distinction between non-putrefactive decomposition or decay and putrefaction? 5. How do disease germs produce their characteristic effects on the system?

MEDICAL JURISPRUDENCE.

1. What are the symptoms of poisoning by wood alcohol? 2. How would you distinguish between a male and a female skeleton? 3. Differentiate between infantile paralysis and idiozy. 4. What mental conditions render a testator incapable of making a will? 5. What is pederasty?

New Secretary in Ohio.—The new secretary of the Ohio State Board of Medical Registration and Examination, Dr. David N. Kinsman, Columbus, assumed his new office January 1.

Illegal Practitioner in Wisconsin.—The Wisconsin State Board of Medical Examiners has caused the arrest of Dr. J. L. Barber of Kaukauna for practicing medicine without a license. The complaint was that Barber purchased his diploma for \$25 from the Illinois Health University of Chicago.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending January 6, 1906:

- Manly, C. J., asst.-surg., leave of absence extended thirty days.
- Malbee, James I., asst.-surg., assigned to duty at surgeon of the transport *Sheridan* during the next voyage to Manila.
- Greenleaf, Henry S., asst.-surg., assigned to duty as surgeon of the transport *Sheridan* during the next voyage to Manila.
- Reynolds, F. P., surgeon, ordered to Headquarters Department of the Columbia, Vancouver Barracks, Washington, for temporary duty as acting chief surgeon.
- Collin, J. M., asst.-surgen, leave of absence extended fifteen days.
- Talbot, E. M., asst.-surgen, leave of absence extended thirty days.
- Levis, Wm. B., deputy surgeon general, leave of absence extended two months.
- Brooks, Wm. H., asst.-surgen, advanced from grade of first lieutenant to that of captain from January 1, 1906.
- Page, Henry, asst.-surgen, relieved from duty in Philippines Division about March 5, 1905, and will proceed to San Francisco, Cal., where he will report to the Military Secretary for further orders.
- Williams, A. W., asst.-surgen, assigned to duty as surgeon of the U. S. Army transport *Meade* during the next voyage to Manila.
- Kuhn, Charles F., contract surgeon, returned to Fort Lawton, Washington, from leave of absence, ordered to Fort William H. Seward, Alaska, for temporary duty.
- Rietz, Hugo C., dental surgeon, granted leave of absence for twelve days from Fort Sheridan, Ill.
- Bernheim, Judie R., dental surgeon, left Fort Porter, N. Y., for Plattsmouth Barracks, N. Y., for duty.
- Bedford, John H., contract surgeon, left Fort Sam Houston, Texas, on leave of absence for ten days.
- Carpenter, Alden, dental surgeon, left Fort Flagler, Washington, and arrived at Vancouver Barracks, Washington, for duty.
- Hayward, George W., contract surgn, reported for duty at his new station, Fort de Soto, Fla., after leave of absence.
- Wertebaker, Clark L., contract surgeon, left Madison Barracks, N. Y., on leave of absence for one month.
- Bedford, John H., contract surgeon, relieved from further duty in the Philippines Division, and ordered to Fort Montrie, S. C., for duty, at the expiration of his present leave of absence.
- James, George H., contract surgeon, order for Fort Montrie, S. C., for duty, at the expiration of his present leave of absence.
- John, George H., contract surgeon, order for Fort Montrie, S. C., revoked; at expiration of present sick leave of absence, will proceed home, Toledo, Ohio, for annulment of contract.
- Pinquard, Joseph, dental surgeon, left Fort Leavenworth, Kan., on leave of absence for ten days.

Navy Changes.

Changes in the Medical Corps U. S. Navy, for the week ending January 6:

- Campbell, R. A., acting asst.-surgeon, appointed acting assistant surgeon from January 9.
- Hart, G. G., acting asst.-surgeon, appointed acting assistant surgeon from January 10.
- Black, W. H., acting asst.-surgeon, appointed acting assistant surgeon from January 12.
- Herdson, C. G., medical inspector, having been examined by a retiring board and found incapacitated for active service on account of disability incident thereto, is retired from active service, from December 15, 1905, under provision of Section 1453, Revised Statutes.
- Murphy, J. F., asst.-surgen, ordered to the naval recruiting station, Omaha.
- Miller, C. K., acting asst.-surgeon, detached from the naval recruiting station, Omaha, Jan. 24, and ordered to the naval hospital, Washington.
- Miller, J. T., acting asst.-surgeon, appointed acting assistant surgeon from January 9.
- Schely, L. O., pharmacist, appointed pharmacist December 27, 1905.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending January 3:

- Wilson, R. L., P. A. surgeon, Bureau letter of Dec. 1, 1905, granting P. A. Surgeon Wilson fifteen days' leave of absence amended so "Wall, at thirteen days' leave only."
- Berry, T. D., P. A. surgeon, directed to proceed to Tampa Bay Quarantine, Mullet Key, Fla., and assume command of the service, relieving Asst.-Surgeon E. E. Ebersole.
- Lloyd, B. J., asst.-surgen, assigned to duty in the office of the United States consulate at Guayaquil, Ecuador.
- Wightman, W. M., asst.-surgen, relieved from duty at San Francisco Quarantine Station, and directed to proceed to Callao, Peru, for duty in the office of the United States Consulate.
- Walt, R., acting asst.-surgen, granted three days' leave of absence from Dec. 26, 1905, under Paragraph 210, Regulations.
- Neves, George, pharmacist, granted leave of absence for nineteen days from Jan. 1, 1906.

BOARD CONVENED

A board of officers was to meet at the Bureau, Dec. 28, 1905, for the purpose of making a physical examination of an officer of the Revenue Cutter Service. Detail for the board: Asst.-Surgeon-General J. W. Kerr, Chairman; Asst.-Surgeon J. W. Trask, Recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended January 6:

SMALLPOX.—UNITED STATES.

California: San Francisco, Dec. 16-23, 5 cases.
Florida: Jacksonville, Dec. 23-30, 5 cases.
Kentucky: Covington, Dec. 23-30, 1 case.
Louisiana: New Orleans, Dec. 23-30, 6 cases; Shreveport, 1 case.
Maryland: Baltimore, Dec. 23-30, 11 cases.
Missouri: St. Louis, Dec. 23-30, 1 case.
New York: Niagara Falls, Dec. 23-30, 1 case.
Ohio: Dayton, Dec. 23-30, 1 case.
Pennsylvania: Lancaster, Dec. 2-9, 1 case.
Wisconsin: Milwaukee, Dec. 2-9, 1 case.

SMALLPOX.—FOREIGN.

Africa: Cape Town, Nov. 11-18, 2 cases.
Chile: Antofagasta, Nov. 12-26, 12 cases; 9 deaths; Copiapo, Nov. 9-23, 15 cases, 4 deaths; Iquique, Nov. 26-Dec. 2, 10 cases, 6 deaths; Valparaiso, Nov. 13-22, 100 cases, 25 deaths.
China: Shanghai, Nov. 30, present.
France: Paris, Dec. 2-16, 48 cases, 5 deaths.
Gibraltar: Dec. 10-17, 1 case.
Great Britain and Ireland: Drogheda, Dec. 2-9, 1 case; Hull, 4 cases.
India: Bombay, Nov. 28-Dec. 5, 1 death; Calcutta, Nov. 18-25, 4 deaths; Karachi, Nov. 26-Dec. 3, 1 case; Madras, Nov. 25-Dec. 1, 7 cases.
Italy: General, Nov. 30-Dec. 14, 36 cases; Catania, Dec. 7-14, 1 death.
Mexico: Tuxpam, Dec. 19-26, 2 deaths.
Russia: Odessa, Dec. 2-9, 12 cases, 7 deaths; St. Petersburg, Nov. 18-Dec. 2, 7 cases.
Spain: Cadix, Nov. 1-30, 1 death; Santander, Dec. 10-17, 1 case; Seville, Nov. 1-20, 1 death.

YELLOW FEVER.

Cuba: Habana, Dec. 27-29, 2 cases, 1 death.
Mexico: Merida, Dec. 17-23, 1 case, 1 death.
Panama: Colon, Dec. 7-14, 1 case.
CHOLERA.—INSULAR.
Philippine Islands: Manila, Nov. 11-18, 8 cases, 10 deaths.
CHOLERA.—FOREIGN.
India: Calcutta, Nov. 18-25, 86 deaths; Madras, Dec. 25-Dec. 1, 6 deaths.
Russia: Government of Lomza, Nov. 23-Dec. 6, 12 cases, 3 deaths; Government of Siedler, Nov. 20-26, 7 cases, 2 deaths.

PLAGUE.—PORTUGAL.

Africa: Cape Colony, Port Elizabeth, Nov. 11-18, 1 case.
China: Hongkong, Nov. 18-25, 1 case, 1 death; Nanchang, Nov. 30, present.
India: General, Nov. 1-30, 2 cases, 2 deaths.
India: Calcutta, Oct. 28-Nov. 4, 4,356 cases, 3,090 deaths; Bombay, Nov. 28-Dec. 5, 7 deaths; Calcutta, Nov. 18-25, 22 deaths.
Peru: Antofagasta, Nov. 12-26, 9 cases, 5 deaths.

Medical Organization

What Can the County Society Do?

(Continued from page 61.)

II. MEETINGS TO WHICH THE PUBLIC IS INVITED.

A number of societies have of late derived great benefit from meetings to which were invited the lawyers, the ministers, public officials, the women, or the public in general. At the meetings arranged by Dr. McCormack in Texas and other states this plan has frequently been followed. The public should know of every reason for the organization of the medical profession. There is nothing to conceal. The objects are all, either directly or indirectly, calculated to promote the public welfare. It is wise to take the public fully into our confidence. Physicians are not combining to raise fees or to take advantage of the layman. The public should be taught at these meetings that good medical fees mean good physicians. When the physician is well paid his *clients* should insist that he continue his medical education by some form of post-graduate work occasionally. If the fees are too small the physician can not pursue his studies adequately.

At such meetings, and several can be profitably held during a year—another pertinent topic would be a full discussion of patent medicines, their evils and dangers. The material gathered by THE JOURNAL, the Council on Pharmacy and Chemistry, by *Collier's* and other lay journals can be drawn on for papers to open the discussion. Meetings of this sort, including appeals to the public to aid in securing the passage of good pure food and drug laws, would be timely this winter just as sure as they can be arranged. At such meetings there can be reference to the plan to have a federal department of health and really effective state sanitary organizations. Epidemics can profitably be considered, especially with reference to modes of conveyance of infections. There is hardly a community in which water supply would not be a timely subject,

and everywhere there is need to spread our knowledge of the benefits of scientific ventilation of houses and of the surpassing value of fresh air. Few physicians are yet prepared to discuss cooking in a way to impart needed information, but wherever there is one he can do a world of good, and it is certain that physicians are to be compelled to study methods of cooking and of preparing all manner of foods if they are to come up to the new standards of usefulness.

At one such joint meeting it will in most places be beneficial to consider at length the subject of medical ethics. The public will welcome information as to the relations of medical men to each other and to the public. Other topics will suggest themselves. It is important to note that if the society, through its "Committee on Relations with the Press," has previously brought the editors to sympathize with its purposes, these public meetings will have an extended influence through the reports of them that the papers will gladly publish if considerably approached.

III. PROPRIETARY MEDICINES.

An important and timely subject of discussion is that of proprietary medicines, their hidden composition, and the fraudulent claims made for them. A good text for the discussion would be a sentence by Samuel Hopkins Adams in one of his *Collier's* articles: "Ignorance and credulous hope make the market for most proprietary remedies." He wrote of the public and of patent medicines, but recent exposures in THE JOURNAL show that the observation finds only too ready application to the medical profession. In each society there should be full discussion of remedies whose real formulas are concealed and which physicians are asked to prescribe because some one says they are good. The opening paper might recount the work of the Council on Pharmacy and Chemistry on the acetanilid compounds and Mr. Adams' record of the dangers of their use. The discussion would naturally include reference to the misleading "literature" of proprietary manufacturers.

Of course, the practical object of such a meeting would be the arousing of a strong sentiment against prescribing drugs that are fraudulent or that are "boosted" by false claims. Agreement should be reached to refuse to prescribe any remedies that are anywhere advertised to the public or preparations whose container or wrapper contains full directions for the public's use.

As a co-ordinate topic one member might present a paper on methods of writing prescriptions of simple pharmacopoeial remedies that will fully meet all the indications of the proprietary articles and of the various imitations of them that crowd the market.

(To be continued.)

Society Proceedings

WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Fifteenth Annual Meeting, held in Kansas City, Mo., Dec. 28-29, 1905.

The President, Dr. H. D. NILES, Salt Lake City, Utah, in the Chair.

Officers.

The following officers were elected for the ensuing year: President, Dr. Malcolm L. Harris, Chicago; first vice-pres., Dr. A. L. Wright, Carroll, Iowa; second vice-pres., Dr. C. Foster Hall, Kansas City, Mo.; secretary-treasurer, Dr. Arthur T. Mann, Minneapolis, Minn.

Salt Lake City, Utah, was selected as the place for the next annual meeting.

Transvesical Operation for Prostatism in Aged Males.

DR. CHARLES E. BOWERS, Wichita, Kan., said that more conservative and rational operations on these patients would yield better results and lower the mortality per cent. An exact diagnosis in many cases can only be made on suprapubic exposure of the vesical outlet. The suprapubic operation can be done with greater exactness and will yield better results than the infrapubic in morbid conditions in the male, as has been

the case in the female pelvis. The suprapubic route is as rationally indicated for the relief of prostatic obstruction at the urinary outlet as it is in vesical calculus. The perineal operation offers only 30 per cent. of cures, with a mortality of 7 per cent., and a 50 per cent. chance of having exchanged one urinary difficulty for another, and not infrequently a lesser for a greater one. The transvesical operation entirely relieves all who survive it of their urinary trouble, if it is due to obstruction in and about the vesical outlet, except when they are carcinomatous in character, without sequelae, and with the improved operative technique of to-day no greater mortality.

DISCUSSION.

DR. HENRY T. BYFORD, Chicago, thinks hypertrophy of the prostate is due to some irritation; that it can not come entirely from age alone or from sclerotic changes which occur with age. In some cases of enlarged prostate he thinks there is a gonyth diathesis, and that, perhaps, the treatment recommended by Fletcher, reducing the calories from 3,000 to 1,500 and dieting the patient a little, might obviate the necessity of suprapubic cystotomy in some cases.

DR. JAMES E. MOORE, Minneapolis, did his first prostatectomy suprapubically twenty years ago, and as it was done at that time it was a bloody, blind and unsatisfactory operation. When perineal prostatectomy was suggested and practiced so successfully a few years ago, he took it up and has been advocating it ever since. He maintains that there are certain cases that can be operated better by the suprapubic route as it is done at the present time. However, in his judgment, a surgeon is not broad-gauged, he does not do the best work he can do, until he performs both operations. He believes the perineal route is the choice in the vast majority of cases.

DR. W. W. GRANT, Denver, maintains that in the average case the perineal operation is the more suitable one. In cases in which there is pus, hyaline and granular casts the perineal route is indicated. The dirty cases can be better and more safely operated through the perineum; the clean cases by suprapubic cystotomy by modern methods.

DR. J. W. ANDREWS, Mankato, Minn., believes there are selected cases which should be operated by the transvesical route, but in the majority of instances he thinks the perineal route is the better. He has operated 11 times, with one death. One of the operations was done suprapubically. He found it difficult, unclean, and was unable to get good drainage. Lack of drainage is one objection to the suprapubic route, as it is not and could not be as good as it is through the perineum.

DR. M. L. HARRIS, Chicago, said that when one attempts to generalize from a few cases in surgery, the generalizations are always wrong. The essayist generalized from 12 cases that the suprapubic route is the only one to adopt, consequently he thinks he is wrong. There are many cases in which a good and thorough operation can not be done suprapubically. There are also many cases in which the best operations can only be done suprapubically; consequently, the surgeon must select the best operation for the particular case. Every case of prostatism should be diagnosed accurately before an attempt is made to select the method of operation, and the surgeon can only make such a diagnosis when he employs all the means at his command, and one of these is a thorough cystoscopic examination.

Observations on Renal Surgery.

DR. D. W. BASHAM, Wichita, Kan., said the methods of Jacobson and Edebohl, give permanent results, so far as anchoring the kidney is concerned, but the kidney is fixed too low in the loin, too far from the center of the vertebral column, and too near the anterior wall of the abdomen. There are many operations which anchor the kidney permanently, but which are open to objection from the standpoint that the organ is not held in the natural position. Surgeons do too many nephropexies without making a thorough and painstaking effort to ascertain the conditions of the kidney, its pelvis and the upper part of the ureter.

DISCUSSION.

DR. WILLIAM JEPSON, Sioux City, Iowa, believes there exists a range of mobility of nearly an inch by every kidney that is normally placed. Each case of movable kidney has to

be considered by itself. A certain number of them have to be fixed. He is not a firm believer in decapsulation of the kidney, for the reason that it has been demonstrated experimentally that if a kidney is decapsulated a new capsule is formed in the course of three or four months, and the amount of blood supply the kidney receives from the new source during the time it exists is not sufficient probably to maintain vitality.

DR. A. W. ABBOTT, Minneapolis, Minn., said that in a series of over 2,000 examinations only a very small number of kidneys were felt beyond the limits described in text-books, but this is not in accord with clinical experience. Very few of these patients present any symptoms referable to the position of their kidneys, largely due to the fact, he believes, that the upper part of the ureter falls with the falling of the kidney.

DR. C. W. OVIATT, Oshkosh, Wis., said that occasionally it is necessary to operate on cases of movable kidney. If an operation is undertaken, surgeons should profit by the teaching of Harris of obliterating the space beneath the kidney rather than trying to suspend the organ alone either by the fibrous or fatty capsule. If one simply suspends it, undoubtedly there will be a recurrence of the displacement.

DR. A. E. BENJAMIN, Minneapolis, laid down rules for fixing the kidney. One is, when it shows evidence of hydronephrosis due to a faulty position of the kidney or to a faulty position or kinking of the ureter, fix but do not allow free drainage. Another is, where there is an enlarged kidney, congested or dilated, and where it is tender, fix the kidney. Another condition which calls for fixation is where the kidney seems to produce obstruction of the alimentary canal, either of the colon or duodenum and accessory organs, such as gall-bladder apparatus, the common bile duct, etc. In such cases the kidney is prolapsed, adherent down in the pelvis, and the patients are troubled with obstipation, and by putting the kidney in position and relieving the adhesions the symptoms will partially or entirely disappear. Patients with a dilated condition of the stomach and a diseased condition of the gall bladder, when apparently due to loose kidney, are sometimes benefited if their cases are taken early.

Carcinoma of Descending Colon.

DR. W. W. GRANT, Denver, said that the rectum is the most frequent seat of intestinal cancer. The descending colon is next in order. Cancer of the colon is more common in men; it is not common under 30 years of age. It is primary and circumscribed. Metastasis and constriction are late occurrences. Chronic indigestion, occasional diarrhea and mucous discharges are suspicious symptoms. Ulceration is a late occurrence. Floating kidney and membranous colitis may exist a long time without producing marked symptoms or seriously disturbing the health. It is less malignant than the same disease of the stomach or rectum. It is not painful until late. Stenosis is not attended with striking symptoms until obstruction is complete. Mild malignancy and late infection demand radical operation. More care is necessary in examination at an early period, in order to detect disease.

DISCUSSION.

DR. I. B. PERKINS, Denver, narrated the case of a woman, 62 years of age, in whom there was a tumor in the region of the cecum, supposed by the physician who had charge of the case to be an appendiceal abscess. It was very hard. There was vomiting of fecal matter and had been for twenty-four hours. He made a long incision in the right rectus, and on examination found a hard tumor, but no pus. The appendix was caught in the mass, also the ileocecal valve and a portion of the cecum. He resected the intestine and closed the end of the colon by the Connell suture, then implanted the ileum into the upper portion of the wound. The patient did well, except that there was a slight leakage at the outer and upper portion of the anastomosis and a very small fecal fistula.

DR. A. W. ABBOTT, Minneapolis, has seen three cases of intussusception. He thinks intussusception occurs in cancer of the large intestine oftener than in the small. He has never seen a case in the small intestine, but has no doubt it may occur. He thinks it is wrong to make an immediate anastomosis in these cases. A colostomy should first be made, be-

cause the condition about the cancerous area is so extreme that the parts will not unite if one attempts to sew them.

DR. J. E. SUMMERS, Omaha, said that he had found cancer everywhere in the large intestine, except at the hepatic flexure. In dealing with carcinoma of the transverse colon it is necessary to manipulate the gastrocolic omentum, and unless this is done with the greatest gentleness one is apt to have a complication following the operation which may be serious, namely, hemorrhage into the stomach. His attention was first directed to this complication some years ago following an operation for incarcerated umbilical hernia, in which it was necessary to remove considerable portions of the omentum, and the manipulations were rather rough. The operation was proceeded with without any special difficulty, but it was followed in two hours by profuse hemorrhage from the stomach, from which the patient died.

Choice of Ligature and Suture Material in the Surgery of the Peritoneum.

DR. H. G. WETHERILL, Denver, no longer uses non-absorbable ligature or suture material for purely serous surfaces. The absolute sterilization of catgut is no longer difficult, and it is now realized that so called catgut infections usually have their origin in a contamination of the gut through handling or in allowing it to come in contact with unclean surfaces or substances in or about the wound. The chromicizing process prolongs the life of even the smaller strands to any desired time, providing the mucous surfaces or secretions are not in contact with it. These features make of catgut an ideal suture and ligature material for intraperitoneal use, and all that becomes necessary is the exercise of due care and skill in the selection of the catgut and the application of sutures and ligatures and the making of knots. So far he has never had a secondary hemorrhage or other accident from the use of catgut, either in the way of a slipping knot or a too rapid absorption, and he believes this immunity from accident to have been due to the exercise of extreme care in its application.

For about three years he has had great satisfaction in using the Downes electrothermic cautery clamp in selected cases, thus doing away with all ligature and suture materials around pedicles. For vaginal hysterectomy, particularly in cancer of the uterus, it is ideal. It promotes rapidity and safety in the work, and gives much greater security against the danger of recurrence in early cases. Patients operated on with the Downes clamp by either the vaginal or abdominal route have smoother and more rapid recoveries, and noticeable freedom from the intense pain and backache so common after all pelvic operations when the terminal nerves of this region are left for days or weeks in the light of a securely tied ligature or closely applied suture. He has had one or two experiences with the Downes clamp, however, which lead him to believe that there is increased danger from thrombosis and embolism after its use, occurring occasionally several weeks after operation, and until this doubt is settled he would exercise great care in the selection of the cases on which it is to be used.

A New Technic for Breast Amputation.

DR. JAREZ N. JACKSON, Kansas City, Mo., described a new technic for use in radical operation for carcinoma of the breast. His experience is limited to eight cases. He emphasizes the following advantages: (1) The flap forms a covering for the chest defect, as a rule, without any tension, and thus almost entirely obviates the necessity of grafting, which is so frequent in other methods. He has not found any case operated on by his method that requires grafting. This is not intended to cover cases where there has been extensive previous ulceration or where one can not get healthy tissue for a flap of any character. (2) The drawing of the skin up to the arm does away with the fossa axillaris, and thus with the large space which nature would have to obliterate by the formation of scar tissue with the resultant pressure on the axillary vessels and nerves. (3) The ligation of all vessels at their nearest point of origin does away with the use of a large number of hemostatic forceps, which cause loss of time, to say nothing of the inconvenience of having a large number of instruments in one's way. He has in no instance used more than one dozen forceps in this operation, and can

usually do the work with about six. The operation is thus shortened, so that, as a rule, he finds that to complete it requires from forty minutes to one hour or thereabouts. In fact, personally, he has never run beyond one hour, even doing the operation slowly, as he has in most cases, for the purpose of demonstrating this new technic, and he has done the operation in a period of time as short as forty minutes. (4) The most noticeable feature to the onlooker, when the operation is done, is the marked absence of hemorrhage, so that it can almost be called a bloodless operation. (5) The entire technical portion of the operation is completed before the chest is exposed by the removal of the breast; therefore, long exposure of an enormous area of raw chest surface, with the attendant shock, is done away with. As soon as the breast is removed, the surgeon is ready to close the wound.

Fractures About the Elbow Joint.

DR. W. D. HAINES, Cincinnati, Ohio, said that the open method of treatment is to be commended in all cases of extensive joint involvement. After freely exploring the joint cavity, freeing it from clot, removing detached spicula, and fixing the fractured fragments, a strip of fascia from the arm may be inserted between the joint surfaces after the method of Murphy in excision, or the Mosetig bone filling may be used, with a view to preventing adhesions until sufficient repair has taken place to permit of passive motion. The operation is completed by suturing the capsule, fascia, nerves and skin with ample provision for drainage. The arm should be dressed in the fully extended position, placed on an incline and a light weight applied. This position and dressing should be changed at the end of one week. After light massage the arm is redressed at a slight angle, and permitted to remain for four or five days, when it is changed to as nearly a right angle as possible without pain to the patient too severely. Subsequent treatment consists of massage and passive motion every third day for a period of three weeks. The author gives precedence to local pain and tenderness over crepitus in diagnosis. The use of weights to overcome muscular rigidity permits of infiltration, diminished elasticity, interfering rather than assisting in the reduction of these fractures. The proper treatment of pain and swelling accompanying fracture is early reduction and the application of extension, ice, or other adjuncts deemed advisable. Immediate amputation is reserved for those extensive crushing injuries, such as bumper wounds, in which the circulation and joint are so badly damaged as to be beyond all hope of repair. The author expressed the opinion that fractures about the elbow joint have been over-treated in the past.

Treatment of Varicose Veins.

DR. C. H. MAYO, Rochester, Minn., said that the various operations in use at the present time are necessary from the diverse conditions and symptoms manifested by the disease. The condition is probably from a defect in the vein walls, valves or emervation. The Trendelenburg operation is deservedly popular, especially for cases of vicious venous circle of the deep and superficial veins of the thigh. Enucleation of the veins in a subcutaneous manner through several short incisions is a satisfactory treatment for the majority of cases. The subcutaneous removal of the internal saphenous from above at the side of and below the knee, by destroying the main superficial channel and deep communicating branches, is the best method, accomplishing in one operation all that can be obtained by either the Trendelenburg above or the Schede below. Goerlich's report shows 84 per cent. of operations as satisfactory, and 16 per cent. as failures. From experience in 184 cases this seemed a fair statement of the late results from the various methods employed at present, except in the percentage of failures. Dr. Mayo thinks 16 per cent. is too high, as many of those not satisfactory are much improved over their former condition.

Undescended Testicle.

DR. A. E. BENJAMIN, Minneapolis, said that the causes of undescended testicle may be due to improper development of the organ, to a rudimentary vaginal process, to peritoneal adhesions between the testicle and bladder or intestine, and to obstruction of the canal. The testicle may be found any-

where along its course of descent to a point just outside the external ring. Hernia is a common complication of this condition. The organ will not develop as well when located at any point above the scrotum. The possible sterility of the erythroïd and the frequency of malignant, tubercular and traumatic disturbances, complicating this condition, all argue for an early operation to place the gland in its proper location. The operation for undescended testicle has been perfected in the last few years. It has been demonstrated that by careful dissection and an occasional sacrifice of the spermatic vessels the organ will remain in the scrotum.

The Free Interval in Meningeal Hemorrhage.

DR. F. GREGORY CONNELL, Salida, Colo., reported two cases, one of which he said was quite usual, with an interval of two hours, in which recovery followed operation. The other was one in which the patient retired for the night, five hours after a slight trauma, and was found dead in the morning. Autopsy revealed a fracture, with a large extradural clot from the lateral sinus. This second case was not very rare; but in 80 cases collected by the writer only 2 similar instances were encountered. The free interval is defined as a practically symptomless period of consciousness, which follows a primary, transitory unconsciousness; and precedes a secondary, increasing and permanent loss of consciousness. This condition is usually found in association with a head injury. The cause of the bleeding is usually traumatism, with or without fracture. The length of the free interval is studied, in an analysis of the 80 cases, the average length being thirty-five hours. The typical train of events in a meningeal hemorrhage is (1) trauma; (2) concussion, unconsciousness; (3) consciousness, free interval; (4) compression, unconsciousness, but this may be variously modified. In the diagnosis the focal signs are of more value than evidence of injury. The occurrence of collateral hemiplegia must be remembered. Fracture of limbs, previous paralysis or congenital attachment of the iris has caused confusion in diagnosis. Contusion or laceration of the brain, abscess, fat embolism and other conditions may closely resemble meningeal hemorrhage.

In the 80 cases collected, 52 were operated on and 28 were not. After operation there were 39 recoveries and 13 deaths. Without operative interference, 4 recovered and 24 died.

Effects of Osmic Acid Injections.

DR. JOSEPH RILUS EASTMAN, Indianapolis, Ind., said that the injection of ten drops of osmic acid in a 2 per cent. solution into sensory nerve trunks is safe. The likelihood of irritation of the kidney, however, should not be forgotten in cases exhibiting kidney lesions. Injections into the inferior dental or other nerves should not be made through the mouth, as infection of the wound and necrosis may result, with consequent failure in the action of the acid. Immediate relief should not always be expected, notwithstanding that the cases of Bennett and Murphy were all immediately relieved. None of the writer's cases, even those in which the acid was accurately injected into the nerve trunks and into the perineural fat, was promptly relieved, relief coming in from one to two weeks.

There is very little doubt but that the stretching of the nerve trunk incident to the injection is productive of good, supplementing, as it does, the action of the acid. There is no good reason why the stretching should intentionally be avoided, except, perhaps, for experimentation. In the case of small nerves, it will be found exceedingly difficult to inject directly into the nerve trunk, that is, the needle eye will pass to the distal side of the thread-like nerve, or perhaps not enter the nerve substance at all, or, notwithstanding the utmost care used, the fibers may be teased apart by the needle point so that the fluid will simply be spilt about the nerve. In such a case, in order to bring the acid in contact with all of the fibers, it is wise to clip the nerve so that the end may be bathed in the fluids. A general anesthetic should be administered so that neurotomy or section of the nerve may be practiced, if desired.

Eastman's experiments have shown no other changes in the nerve tissues as the result of injections of osmic acid than the disintegration of fat and oil globules in the perineural space and in the white matter of Schwann. The degenerations ap-

pearing in the nerve itself are only such as may be attributed to nutritional changes and exposure, the indirect result of the selective action of osmic acid of destroying fat. There is no reason why this fat should not be restored, and the nerve again become capable of transmitting sensation, that is, theoretically the neuralgia may return after injection of osmic acid. Osmic acid injections are uncertain in effect as to the cure or relief of neuralgia. A large percentage of cases of neuralgia may be relieved for months by osmic acid injections. The injection of osmic acid for the relief of the *douloureux* is quite justifiable, even if it should become necessary to repeat the injections at intervals of a few months, particularly in view of the unfavorable results of the so-called radical operation. The local irritation produced by the acid and the remote toxic and irritant effects are not serious in their consequences and have no meaning as to the effect of the osmic acid in relieving neuralgia. The solution of osmic acid should be made fresh for each operation, as deterioration is rapid.

Twentieth Century Surgical Problems.

DR. H. D. NILES, Salt Lake City, Utah, selected this subject for his presidential address. No one who has kept in touch with recent experiences in the surgery of the brain, lungs, pancreas, spleen, peritoneum and other organs can escape the conviction that, with a clear, definite idea of the physiology of these parts, the result of surgical endeavors will be infinitely more satisfactory than we are able to obtain with present knowledge. In brain surgery many failures can not be charged to lack of operative skill, but to inability to locate the pathology early enough to insure safe removal or correction. The same may be said of the morbid conditions of the spleen, pancreas, and, in a degree, of the stomach. Until we are better informed by the physiologist of the normal functions of these organs, we can not hope always to differentiate between the normal and the abnormal. The evidence that points to the one and excludes the other can only come to us through concentrated specialized efforts which the average surgeon is technically unfitted to undertake.

The line that divides surgical from non-surgical diseases is still somewhat vague and indistinct, and one of the most common sources of error in the treatment arises from the fact that we are often in doubt as to when and how far we may safely trust to the reparative resources of nature, and under what conditions prompt operative interference should be resorted to. Thus far success in surgery has been measured largely by the ability to cope with advanced disease after it has become an immediate menace to life and health. But the time can not be far distant when the importance of recognizing the antecedent pathology of cancer, ulcer, surgical kidney, pus tubes, prostatitis, and many other grave lesions, will be impressed on the profession, and the public will be educated to choose preventive rather than last-resort surgery. If we are ever to solve the problems that baffle our endeavors to-day, and place surgery on a much higher plane than it now occupies, scientific workers must become more practical, practical workers must become more scientific, and physicians and surgeons must become more nearly united in their ideas of pathology and treatment. And this can only be accomplished by an organized movement, tending to bring all workers in closer touch and sympathy with one another.

Chylous Cysts of the Mesentery.

DR. MILES F. PORTER, Fort Wayne, Ind., said that these cysts are very rare, more so than are serous cysts. The origin of chylous cysts must be regarded as manifold. They may be single or multiple, unilocular or multilocular, and multiple cysts may become multilocular single cysts and later unilocular by pressure absorption. There is nothing distinctive in chylous cysts save their contents and location. An exact diagnosis is neither possible nor necessary. A centrally located movable tumor crossed by bowel will be almost diagnostic of mesenteric cyst. Puncture for diagnostic purposes is condemned. Abdominal pain is a common symptom, and recurrent attacks of pain, accompanied by vomiting and other symptoms of bowel obstruction, are very significant. Chronic increasing constipation is a frequent symptom. A history of trauma is common. The treatment is surgical and the technic

depends on the findings in each case. The fear of permanent chylous fistula in cases treated by drainage is unfounded.

Treatment of General Peritonitis.

DR. DONALD MACRAE, JR., Council Bluffs, Iowa, advocated the Fowler position in all suspected peritoneal infections; also the institution of free drainage at the time of the operation by means of large-sized rubber tubing only. Drainage of the most dependent part of the pelvic peritoneal pocket is imperative. He urges the removal of the primary pathologic factors when possible and advises against the use of gauze and flushing. He said the drainage tubes should be sucked at frequent intervals.

Appendicitis.

DR. I. B. PERKINS, Denver, favors early operation in all cases, including the interval cases. Fatalities are usually chargeable to delay.

(To be continued.)

AMERICAN SOCIETY OF TROPICAL MEDICINE.

Meeting held at Philadelphia, Dec. 8, 1905.

Mosquito Work in Relation to Yellow Fever on the Isthmus of Panama.

COL. WILLIAM C. GORGAS, U. S. A., in charge of the sanitation of the Canal Zone, spoke more particularly with reference to yellow fever and malaria, which two diseases had caused the principal mortality during the building of the railroad and in the attempted construction of the canal by the French. The conditions were much the same as had been encountered in Cuba, except that in Panama mosquitoes breed as readily in January as in July. During the French occupancy the heavy mortality was a potent factor in the failure of the canal work. From his investigations he believes that the French statistics represent not more than half the actual mortality. Under the United States government authority for doing sanitary work was granted in February, 1905. All cases of yellow fever were required to be reported to the American health authorities, and in addition all cases of fever of any kind occurring in an American were also required to be reported. Cases were, therefore, received within the first day or two of the disease. The general mortality was about 25 per cent. of all cases; the mortality of Americans treated in the hospitals was not more than 10 per cent. The suspected patient was placed in a thoroughly screened ward. In the yellow fever wards the additional precaution is taken of putting each new patient in a wire cage just large enough to cover his bed until the infectious period of the disease has been passed. Also these wards are fumigated every two weeks, so that if a mosquito should get in and bite a patient she would not have time to become infected herself, for from twelve to fifteen days' time is necessary for infection and ability of the mosquito to carry it. The house from which the patient is removed and the contiguous houses are likewise fumigated.

The stegomyia was described as a very domestic mosquito which generally does not leave the house where she is born and bred, and rarely the room in which she has lived. The fumigating sprays are composed of an experienced foreman and twenty men. The material generally used is sulphur, although in many stores and in the better class of residences many articles are ruined by its employment. Parisian insect powder, pyrethrum, is sometimes substituted for sulphur. If a patient elects to be treated at home, the central office is informed, and the patient is thoroughly protected by screens. Only one exit is left to the room and a guard is stationed there, who keeps the key and admits only those who are authorized by the doctor. The fumigation of the rest of the house is carried out and the screened room fumigated when the case has terminated. The stegomyia breeds principally in clean rain water, and in Panama the people have depended largely on rain water for domestic purposes. All receptacles for the water are, therefore, covered, and an inspector appointed for each district, concerning the conditions of which he is obliged to report at least twice a week. At the time of the first inspection, about the first of March, 1,000 breeding places were reported; in

October, about the time Colonel Gorgas left Panama, there were less than 400. In the city of Panama it is estimated that 90 per cent. of the mosquitoes were stegomyia, while in Havana they constituted only 5 per cent. of the mosquitoes. The results of the work are seen in the apparent elimination of yellow fever. In June there were 67 cases; in July about 40; in August about 27; in September about 7; in October 3; none in November; none so far in December. In the town of Colon the last case occurred July 23. Colonel Gorgas believes, however, that it is necessary to allow at least two months to pass without a case before it can be said with certainty that yellow fever has been eliminated.

Detailed descriptions of the measures against malaria were not given, but they were the same as those carried out in Havana, and now used in the United States generally, principally superficial ditching. The results have been satisfactory. Colonel Gorgas thought it safe to say that the canal is being dug with as little trouble from sickness as would obtain in a similar project between Philadelphia and Baltimore, and he believes that further improvement can yet be secured.

SAN BERNARDINO COUNTY MEDICAL SOCIETY.

Annual Session, held Dec. 13, 1905, at Arrowhead Hot Springs, San Bernardino, Cal.

The President, DR. HOELL TYLER, Redlands, in the Chair, and DR. J. M. HURLEY, Secretary.

DR. G. W. TAPE, medical director of the Arrowhead Hot Springs, delivered the address of welcome, which was responded to by Dr. Hoell Tyler.

Officers.

The following officers were elected for the ensuing year: President, Dr. Thomas M. Elyte, Redlands; first vice-pres., Dr. Joseph A. Champion, Colton; second vice-pres., Dr. Charles E. Ide, Redlands; secretary, Dr. D. C. Stroug, San Bernardino; treasurer, Dr. John H. Evans, Highlands.

Importance of a Proper Diet in the Treatment of Disease.

DR. FRANK W. THOMAS, Claremont, took the ground that a careful and intelligent study of dietetics is the keynote of the medicine of the future. Drugs, while both useful and necessary in emergencies, can not produce the permanent alterations of nutrition which can be obtained by an intelligent selection of foods. In nearly all chronic diseases, such as gout, rheumatism, nephritis and diabetes, an intelligent regulation of the diet and habits of the patient is far the most potent means of arresting the progress of the disease. He referred to the brilliant researches of Pawloff on the different strengths of digestive juices called out by different classes of food, illustrating the exquisite adjustment of the alimentary canal to its work, and also the changes which can be produced by an intelligent selection of the different classes of foodstuffs.

DISCUSSION.

DR. WOODS HUTCHINSON, Redlands, believes that a new era is opening up in this most important realm, and that some of the old landmarks are going down to oblivion. Among them is the old three-fold classification of foods of Liebig and Voit, into the flesh-formers or proteids, the fat-formers and the heat producers. It is important to recognize that any class of food can serve any of these functions, and that all food taken into the body is broken down into its simplest molecules, and built up again into the tissues, giving out energy in the process. Secondly, it is doubtful whether the food elements which can be built up into the body tissue pass through the form of peptone. Certainly, a considerable percentage of the peptone formed in the alimentary canal is on its way to the formation of creatin and creatinins and finally other waste products. Therefore, the administration of predigested foods, peptones and peptonoids, is of exceeding doubtful value, nor is the giving of pepsin itself of much greater utility, inasmuch as all gastric analyses show abundance of this ferment present in all cases where acidity is anywhere near normal. The researches of Pawloff have shown that an attractive taste on the part of food is absolutely necessary to stimulate the flow of gastric juice.

DR. GEORGE K. ABBOTT commented on the delicacy and accuracy of the modern tests of digestive power, and the importance of finding out whether lactase is present in the gastric juice before putting the patient on a milk diet.

DR. GEORGE L. COLE, Los Angeles, said that while he thoroughly agreed with Dr. Thomas as to the great importance of dietetics, he had no sympathy with the therapeutic nihilism which derides all use of drugs. The man who has no confidence in drugs should resign from the profession. He agreed with Dr. Hutchinson that the patient should be encouraged to take a wide variety of foods, and that Nature knows how to take care of an excess better than she does of a deficiency. He believes that pepsin and other digestives are sometimes useful in assisting patients who either can not, or imagine they can not, digest certain foods. He believes with Dr. Hutchinson that most patients are underfed rather than overfed.

DR. F. C. E. MATTISON, Pasadena, stated that the more he studies the diet of his patients the less frequently he finds it necessary to give medicine in the chronic disturbances of nutrition. He believes in going into considerable detail with his patients as to what and how much they are eating, making them give him, as nearly as possible, a complete list of the articles they have eaten during the last six or eight meals. He frequently finds in this the secret of at least part of their condition. He agreed that more patients are underfed than overfed, especially among women and children, and that many who attempt to regulate their diet have done so at the expense of some of the elements of which they were most in need, particularly in the line of meats and fats.

DR. NORMAN BRIDGE, Los Angeles, sounded a note of warning against the too strictly regulated diet. In diabetes, for instance, the tastes are in a state of carbo-hydrate hunger, and the deprivation of carbohydrate might re-educate them to the combustion of sugars. An absolute starch-free diet is practically impossible to obtain, and when approximately reached would ultimately injure the general nutrition if long persisted in. He agreed that a wide range of foodstuffs is absolutely necessary to health, and that patients should be encouraged to increase their food-range rather than to diminish it; that the majority of patients are underfed rather than overfed; that the senses of taste and smell are necessary to aid digestion and produce a flow of Pavloff's appetite juice, and that attractive cooking is of great importance in dietetics. Our ideas of digestibility of a food are too exclusively based on the length of time it takes the food to leave the stomach, forgetting that the real digestion is in the small intestine, and that so long as the stomach can empty itself in a reasonable length of time and pass it on to the small intestine, a patient's nutrition can be well kept up to an indefinite period.

DR. JOHN HAYNES, Los Angeles said that in his experience a large majority of patients, particularly of successful business men over the age of 40, eat too much and suffered severely in consequence. He believes that the mere thought of savory food is sufficient, sometimes, to start a flow of gastric juice.

DR. LEMOYNE WILLS, Los Angeles, believes that we should encourage our patients to depend less on the artificial flavors of the cook and to relish their food in its natural state. That the use of milk, raw eggs, nuts and fresh vegetables form a valuable stimulus to the jaded appetite, and call into play both the muscles of mastication and the digestive secretions of the stomach and pancreas in a way that stewed, baked and boiled food does not. He believes that animals living in the open air and eating food in its natural state, are more vigorous and less subject to disease than man.

DR. C. C. BROWNING thinks that a full and rich diet range is necessary in a great majority of cases, both to sustain nutrition and to provide a sufficient amount of waste material to properly stimulate the colon. This is well understood by farmers and stock men who know that horses and cattle fed on grain alone rapidly lose their appetite and become diseased. He called attention to the fact that it is necessary to not only ingest an abundance of food, but to create an appetite for it, and one of the best ways in which this can be done is living in the open air, with exercise, if possible, but where fever exists, as in the case of the consumptive, without it. One of the great advantages of the open-air treatment of consump-

tives lies in the appetite it gives and the large amount of food the patient can consume without becoming bilious. Get patients out of the delusion that drafts are harmful. Teach them to sleep every night with a current of fresh air blowing across the face and half their dyspepsia will disappear.

Shall We Open the Abdomen in the Presence of Acute Inflammation of the Peritoneum?

DR. C. VAN ZWALENBURG, Riverside, held that an intelligent conservatism in this class of cases is productive of best results. He stated that during his practice he has treated 35 cases of appendicitis without operation, all of which recovered. He has also found that many cases of peritonitis, due to various causes, including tuberculosis, recovered by a policy of letting alone. He finds great satisfaction in the Ochsner method of treating appendicitis.

The Conservative Surgery of the Tubes and Ovaries.

DR. A. W. LOBINGIER referred to stricture of the isthmus of the tubes, and methods of operating for this condition. His experience with grafting of the ovary has not been a favorable one. He deprecates radical and unnecessary interference with organs or inflammatory adhesions, and particularly emphasized the importance of limiting the handling and exposure of the viscera to the smallest extent possible, and the avoidance of poisonous or irritating antiseptics and flushes in the peritoneal cavity. He described several original procedures for reducing interference and exposure to a minimum, at the same time providing for the free escape of pus and serum.

DISCUSSION.

DR. C. D. LOCKWOOD, Los Angeles, called attention to the necessity of perfect drainage in abdominal surgery. He agreed with Dr. Lobingier that the pendulum of surgery is swinging back again in the direction of conservatism, and the reduction of removal and interference to only what is absolutely necessary.

DR. LAMOYNE WILLS referred to the admirable original work done by the late Dr. J. McCone of Los Angeles in experimental transplantation of the ovary, stating that his success in this operation had been really remarkable anticipating the results of European experimenters.

DR. BEARDSLEY agreed with Dr. Van Zwahlenburg that there has been entirely too much rash and unnecessary surgery of the abdomen. He has had most satisfactory experience in a number of cases of appendicitis with the Ochsner or starvation method of treatment. He also spoke highly of Murphy's system of drainage of the peritoneum, making an opening only sufficiently large to admit the drainage tube and closing up the wound close around the tube.

DR. D. C. SROXG, San Bernardino, thinks that while the Ochsner treatment is excellent in its place, it is being used in an unintelligent manner to a dangerous degree as a substitute for operation in appendicitis. This is not Ochsner's intention or method, as it is only used in cases seen forty-eight hours or more after commencement of the attack, or such as are from various causes unsuitable for immediate operation.

DR. W. W. BECKETT, Los Angeles, believes that in early cases the ideal procedure is to open at once, reserving the Ochsner method for cases too late for operation.

In the evening the society members were guests of the Arrow-head at a fine banquet, which was followed by toasts.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Regular Meeting, held Nov. 2, 1905.

The President, DR. R. C. NORMAN, in the Chair.

Control of Postpartum Hemorrhage.

DR. J. S. RAUBENHUSH said that the treatment must be directly or indirectly hemostatic, and the measures employed depend on the cause, existing conditions and the fact that the hemorrhage may be brought on, accompanied, or followed by shock, syncope or anemia. To check the hemorrhage and overcome its effects one must (a) induce uterine contractions, (b) stimulate the various organs of the body to their respective functions, and (c) supply fluid to the heart and brain. Ergot

should be given when the uterus is empty as a preventative of hemorrhage, and to prevent the free accumulation of blood clots. Aseptic ergot given hypodermically will show its effect almost immediately, and its use is imperative in serious cases. Strychnin is of value in cases due to extravasation and inertia uteri. It should be given in doses of gr. 1/40 to 1/20, and repeated as indicated. It may be combined with ergot or digitalis, or with morphin where cerebral anemia exists. It is wrong to over-stimulate because the uterine muscles will become exhausted. Digitalis is given hypodermically in doses of m. x-xxv, or digitalin, gr. 1/100 to 1/50. It is well to combine it with strychnin since its effect will continue for a longer time. It lessens the heart beats, contracts blood vessels, and it acts on the uterine muscles. Adrenalin is useful when the hemorrhage is not too severe, or to prevent secondary postpartum hemorrhage. It is the best drug for shock. Calcium chlorid and gelatin produce coagulation of the blood. The commercial gelatin, which contains 0.6 per cent. of calcium chlorid, frequently contains albumoses which prevent hemostatic action. He has never employed it in this condition. As stimulants he favors strychnin and digitalis. Nitroglycerin should not be used, unless for syncope and shock. Caffein citrate is excellent as a cardiac and cerebral stimulant in syncope. Strophanthus, quinin and camphor are not indicated. Alcohol (whisky or brandy) can be of no service in severe cases, but may be of real harm. Ether, hypodermically, is useful to stimulate a flagging heart. Ammonium carbonate may be given per rectum when shock is present. Turpentine is of value when purpura hemorrhagica and hemophilia are the causes. Atropin is invaluable for shock and can be combined with morphin. Normal salt solution, administered by enteroclysis, hypodermoclysis or venoclysis, acts as a mechanical stimulant and should be used whenever collapse, shock or anemia follow the hemorrhage.

The best prophylactic and therapeutic measure for postpartum hemorrhage is massage and compression of the uterus. It is effectual, an external method, free from the dangers of infection, and the manipulating hand is able to detect the exact state of the uterus. The hand is kept on the uterus for a half-hour or hour after delivery. In this way no concealed postpartum hemorrhage can occur. First apply uterine massage, then give hypodermics. If not effectual, then give also hot intruterine injections. Compression of the abdominal aorta is also free from the dangers of infection, prevents flow of blood to uterus, sending it to the heart and brain. Elevation of feet, lowering the head, and ice to the abdomen are of great value to check, control or prevent hemorrhage. Fritsch's "rational bandage." The empty uterus is flexed over the pubic bone, and pads are placed in the abdominal depression back of the uterus and fixed by bandages. The uterine cavity obliterated, immediate hemostasis, no internal manipulations, nothing need be done for twelve or twenty-four hours. Bandaging the arms and legs to send the blood to the heart and brain may be injurious; venoclysis is far better. Abdominal binder, as a preventive, should be applied in all cases of labor, also after hemorrhage when it has been checked. Flagellation of the abdomen is dangerous in cases of shock. Heat to the body and extremities may be tried when shock is present. Electricity should not be used because it increases liability of infection. Inhalations of fresh air, oxygen, camphor and ammonia may be of value whenever "air hunger," syncope or shock are complications.

Within the uterus, hot water irrigations may be given when uterine massage and hypodermics fail. Temperature of water 115 to 120 F.; must be hot to be styptic. Intruterine manipulations are unavoidable when the placenta is adherent, and are sometimes necessary for removal of clots and to irritate the uterus to contract. It is well to have simultaneously hot-water irrigations. Vinegar is very effective. When more aseptic measures are wanted it may be injected or carried in on a saturated cloth and squeezed over the inner uterine surface. Ice within uterus may be of value when hot water fails. Astringent acids are condemned. Iodin has been used, but cleaner and more effectual measures are available. Iron in the form of Monsell's solution is unclean, injures lining of uterus,

the formed clots are liable to become dislodged and favor secondary hemorrhage. It is almost certain to lead to infection and should not be employed. Tampons are very difficult to effectually pack in a flabby uterus, in fact, quite impossible; much time is required; sepsis is common, and secondary hemorrhage is apt to occur when packing is removed. They favor concealed hemorrhage. Operation is seldom necessary. During second stage of labor, version, forceps, Cesarean section or, perhaps, craniotomy may be necessary. After delivery, correction of displacements, repairs, clamping of vessels, laparotomy, curettage may have to be done.

DISCUSSION.

DR. JOHN B. SUGER has used extract of mammary gland extensively in cases of hemorrhage due to subinvolution of the uterus following labor, miscarriages, etc. It has entirely taken the place of ergot in that class of cases in his practice. It has a direct influence on the uterine muscle, is a stimulant to the circulation, and has no untoward systemic effect, even when used in large doses.

DR. DANIEL LONGAKER believes that the routine use of ergot after the emptying of the uterus will go a long way toward preventing hemorrhage. Ergot should be used after the uterus is completely emptied. He has never seen the symptom of "air hunger" except as a precursor of a fatal termination in several cases of rupture of the uterus. Little can be done when this symptom develops. He thinks that there are cases, especially those which occur occasionally in placenta previa, with marked tendency to continuation of bleeding, in which the gauze pack, sterile or iodoform, is of great value. Nor would he limit the use of the gauze in this class, for in postpartum hemorrhage, where the placenta has been above the zone of danger, the gauze pack may be safely used. Of the routine measures, the compression of the uterus, the employment of hot water of the temperature of 115, the use of gauze and ergot, using a sterile preparation hypodermically, are the remedial agents on which he relies.

DR. RICHARD C. NORRIS thinks there are many men who fail to understand the application of Credé's method of placental expression and, therefore, fail to apply it in the proper way. He believes that the important fault in employing this method for the delivery of the placenta, in the conduct of the third stage of labor, is that the majority of men attempt the expulsion of the placenta too soon, before the clots in the uterine sinus have had opportunity to form and become reasonably firm. In the absence of bleeding it is his custom to wait ten or fifteen minutes before an attempt is made to expel the placenta by the Credé method. He has never been able to convince himself that ergot did any harm. He invariably administers a dose of ergot as soon as the baby is born, even before an attempt is made to extract or deliver the afterbirth. The theoretical objection to ergot, that it is apt to cause the so-called hourglass contraction of the uterus, he thinks, is a fallacy. The muscles of the lower segment of the uterus are over-stretched, and perhaps paralyzed for several hours, and the action of the ergot for that time is on the upper segment. The administration of ergot from a prophylactic standpoint is a good plan, and the administration earlier than the completion of the third stage has in his hands not been a disadvantage. Furthermore, it helps to promote firm uterine contraction during the first two or three days and perhaps, in a measure, prevents absorption of toxic products that might find entrance to the circulation through the lymphatic or blood vessels.

As to the manual manipulation, he saved a patient's life once by being familiar with Fritsch's method, and in conjunction with it, compressing the abdominal aorta with the ulnar side of the hand, utilizing the other hand in the vagina by holding the posterior against the anterior lip of the cervix and crowding it also against the symphysis pubis. When in need of appliances for an emergency, such as a hot douche, a gauze tampon, a hypodermic, etc., instead of trying to help to get these things, the cool, deliberate obstetrician will direct the frightened assistants while he temporarily controls the hemorrhage by holding the uterus in his grasp. This will stop the bleeding for the time being and give one not only a chance to

regain his own equilibrium, but the assistants to get any appliances that may be required. The method is of extreme value in the emergency or serious postpartum hemorrhage. He has saved life by the intrauterine tamponade. Where the hot douche fails, external and internal manipulation fail, and the woman is rapidly dying, the one thing to do is to promptly tampon the interior of the uterus from fundus to vagina. He does not use iodoform gauze if he can help it. After twenty-four hours the gauze is gradually taken out.

He thinks that adrenalin solution has not been demonstrated to be more valuable than ergot. He has frequently employed it in shock in conjunction with salt solution by hypodermoclysis and has found it of value. In conditions of shock independent of postpartum hemorrhage, he would also not hesitate to use it. A tampon saturated with adrenalin solution and packed in the uterine cavity would probably have some effect in promoting firm contraction and the formation of thrombi. He is not satisfied, however, that its action on the musculature of the uterus can equal that of ergot. Every obstetrician in the daily routine of his practice should have ready for use iodoform or some other gauze for tamponing the uterus. He also urged the men who see these few cases of real postpartum hemorrhage to bear in mind the importance of Fritsch's method.

DR. WILLIAM R. NICHOLSON agreed with Dr. Norris relative to the rarity of true cases of postpartum hemorrhage. The obstetrician's duty is to place his hand on the abdomen over the uterus as soon as the child has been born and to keep it there until the placenta is delivered. If this is carried out as a prophylactic measure there will be many less cases of moderate bleeding following deliveries. The treatment with the mammary gland may be of value in such cases as Dr. Norris made mention of, which oozed to death. In the treatment of hemorrhage the two methods of most value are the method of Fritsch and tamponing the uterus with gauze. He recalled one case of postpartum hemorrhage in which appendectomy had been performed about a year before, and in this case there was no other appreciable cause than the adhesions that had formed. He believes that as the removal of the appendix during pregnancy is becoming more and more frequent, it is well for a man attending a case with such an operative history to be especially on his guard against postpartum hemorrhage. In the case referred to the adhesions probably were the cause of the bleeding.

Embolism Following Abdominal Section.

DR. WILMER KRUSEN reported five cases, four of which ended fatally, occurring in twelve years of gynecologic practice. The symptoms in all these cases, as nearly as could be observed, were very similar. The attack was characterized by precordial distress, severe pain and dyspnea associated with quickened pulse. The patient has an extremely anxious expression, gasps for breath with the aid of all the auxiliary respiratory muscles; the face becomes cyanosed; cold, clammy sweat occurs; the mind remains clear, as a rule, and death occurs in a few minutes in spite of energetic stimulation. The fifth case reported manifested all these symptoms and yet recovered.

When these accidents occur the surgeon feels powerless because there is practically no treatment for the severe cases. It is probably possible, by a careful study of the blood before operation and the avoidance of excessive loss of blood during the procedure and the use of saline infusions after the procedure, to diminish the number of these cases. In anemic cases a longer rest in the absolutely recumbent position, with the avoidance of all exertion or straining for a longer period than is customary, is also to be advised.

DISCUSSION.

DR. WILLIAM R. NICHOLSON has noticed that many of these cases of embolism occur in the simplest form of cases and that the retractors pressing on the internal abdominal vessels give rise to the condition. This was the conclusion reached in our investigations.

DR. COLLIN FOULKROD said that in cases of great anemia and cases which, after operation, show great shock, there is

a pronounced tendency to thrombosis or emboli. The puerperal embolism is quite common and usually occurs from some exertion of the patient, either rising in bed, vomiting, turning over immediately after labor or in the puerperal stage. In one case of hysterectomy which he watched die from pulmonary embolism and heart clot, in which there was no evidence of the slipping of a ligature or of anything being done wrong in the operation, there was a clot not bigger than a filbert in the broad ligament. The postmortem showed undoubted heart clot. In the three cases he has seen of death from embolism, respiration stopped first; the heart beat from one to three minutes after the breathing had stopped, as if there were something plugging up the pulmonary artery and the heart was pumping tumultuously in order to drive that out. The lungs do not expand, because no blood enters them. There is one point which occurred to him in connection with the subject of emboli: the impossibility to tell the exact cause of death in these sudden terminations. One case was that of a man operated on for ulcer of the first part of the duodenum and two days after operation he developed rapid heart and rapid respirations and died within a short time. There was a clot in the heart which, while not exactly the type that you would find postmortem, was one of adherent white fibrin, seemingly antemortem. He apparently had not been able to stand the shock accompanied with the extreme anemia and the coagulability of the blood. He believes that many patients who die suddenly where surgeons do not attribute the death to any form of pulmonary embolism, and in which they have been led astray by the associated symptoms, die from the presence of the heart clot and subsequent embolism.

DR. RAUDENBUSH cited a case following an abdominal operation. The patient seemed to be fairly well for the remainder of the day and the following day, when between thirty and thirty-six hours after the operation she asked for water. She seemed bright and remarked that she was able to help herself. After taking a little of the water the nurse left the room for a few minutes only, when she heard the patient give a gasping and alarming cry, but before the resident physician could be gotten there the woman had died.

DR. R. C. NORRIS said that every case of sudden death should have a very careful autopsy made before a final diagnosis is made. He believes that some of these sudden deaths after operation are sometimes due to myocardial conditions associated with anemia, prolonged anesthesia and a heart that has been doing its best during convalescence suddenly gives out. Careful observations should be made of the clinical histories of these cases, and, while it is not always possible to get an autopsy, we should have some mental reservation as to diagnosis without autopsy findings.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held Dec. 6, 1905.

The President, DR. CHARLES S. BACON, in the Chair.

Radical Removal of Cancer of the Stomach.

DR. WILLIAM J. MAYO, Rochester, Minn., said the medical treatment of carcinoma of the stomach availed little, and cited numerous examples to show the inconsistency of looking for a medical side of this question. The reasons why the medical profession has been so slow to apply surgical methods to the cure of this common malady are: 1. The frightful mortality of early operations which discouraged patient, physician and surgeon. 2. The difficulties and uncertainties of establishing an early diagnosis. In selected cases the Kocher operation is the method of choice. The death rate from early operations is appalling; the average mortality at the time of Billroth's death was over 60 per cent. Steady progress has been made since 1900. Improvements in technique have been so great that the mortality has been reduced to a remarkable degree. The workers in this field have been comparatively few; yet the work has been so quietly carried on that the profession does not seem to realize the enormous strides that have been made. The mortality in operable cases, in the hands of men of experi-

ence, is not above 10 per cent., and in suitable cases it is nearer 5 per cent.

An exploratory incision is the only way an early diagnosis of cancer of the stomach can be established. Prolonged attempts to establish a diagnosis by laboratory methods are provocative of delay and should be discouraged. The most careful, painstaking methods of examination, including laboratory means, should be insisted on, but should not be unduly prolonged. Where there is suspicion of cancer of the stomach, which can not be disproved by the known methods of examination within a reasonable space of time, the conservative practitioner should explain that suspicion to the patient and ask for a surgical consultation. The clinical history, together with chemical examination of the stomach contents, may lead to the suspicion of cancer of the stomach, and it is on this physicians should act, if they would be truly conservative.

DISCUSSION.

DR. A. J. OCHSNER said that the high mortality following operation for carcinoma of the stomach in the early days was due to conditions which no longer obtain, since the methods of operating have been improved by Mayo, Mikulicz, Krönlein, Czerny and Robson. The mortality primarily comes from the fact that many patients can not stand any operation well, and there is a mortality which comes from operation on patients who have a slight power of resistance. Considerable mortality comes from secondary complications, as pneumonia, etc. This is due to unnecessary traumatism and consequent infection along the esophagus. This has been disposed of by simplifying the operation. The surgery of the stomach, as applied to the treatment of ulcer, has cleared up cases which otherwise would have become cancerous, and has placed the surgeon in a position where he can reasonably approach these cases at a time when their successful treatment is a comparatively simple matter. Shock is one of the causes of high mortality, but this has been reduced materially by a more simplified operation. Infection, which was dreaded so much years ago, has been practically eliminated.

DR. ARTHUR DEAN BEVAN said that the more modern work of the last five years has been sufficiently encouraging to urge surgeons to operate more frequently than they have done heretofore on these cases. He thinks the internists have not sufficient confidence in present means of early diagnosis to warrant them in turning patients over to surgeons for an exploratory operation on the ground that they have probably carcinoma. He admits that this is rather a fine line to draw, but it is one that must be drawn by scientific medical men. The cases which hold out the greatest hope are usually the exploratory ones.

DR. E. WYLLIS ANDREWS stated that the justification for the radical in preference to the palliative operation is based on the results obtained and the greatly decreased mortality from the more modern methods. He does not believe, however, that the time will ever come when palliative operations will be abandoned, for he has seen patients whose lives have been prolonged four and six months, and even for one and two years, by such operations.

DR. ALEXANDER HUGH FERGUSON stated that what the essayist said in regard to early operation in cases of cancer of the stomach should be taken to heart by every practitioner of medicine. He looked up 21 cases that he has had in the last three years, in which he simply opened the abdomen and could do nothing for the benefit of these patients, on account of extension of the disease. These are the cases that come to surgeons for a positive diagnosis. He is frank to admit that in every case, with the exception of one, in which he opened the abdomen there was a positive diagnosis of carcinoma of the stomach. To accomplish any good, these patients should be operated on earlier. He does not know how to make a diagnosis of carcinoma of the stomach so early that a patient is safe. He has been fortunate enough to operate on one case that has been apparently cured by a pylorotomy, that is, the total removal of the pylorus and the cancer-bearing area. It was an early case, because there was early pyloric obstruction. It would be a fortunate thing for the sufferers from carcinoma of the stomach if obstruction at the pylorus were the first

symptom of the disease; then the vast majority of patients would be saved from an untimely death. This pylorotomy was done in Canada twelve years ago, and the man is alive and well to-day.

DR. FEXTON B. TURCK thinks the keynote of the paper is the importance of directing attention to the one question of determining whether or not a given case is one of carcinoma. Taking a certain group of conditions or symptoms, as mentioned by the essayist, one is justified in assuming at least the possibility of the existence of carcinoma, and if a patient does not recover promptly under appropriate medical treatment adjusted to the case in hand, he would not hesitate to demand, an exploratory incision. He recalled two or three cases of a doubtful character in the last year where, by prompt and timely operations, the lives of those patients have been prolonged.

DR. FRANK BILLINGS said that there is no medical treatment except that of trying to relieve the pain of a patient who has cancer of the stomach. Cancer of the stomach, if it is not palliated by drugs, is a surgical disease. As to diagnosis, there is nothing exact in either our present clinical or laboratory methods. A few years ago physicians looked on the chemical conditions of the stomach contents as important in diagnosis, when, in fact, the chemical reactions of the stomach contents are of minor importance. The motility of the stomach is one important factor in separating medical and surgical cases. When this is disturbed and stagnation occurs, the case is either a medical or surgical one, and the diagnosis will clear up which it is. If it should turn out to be a case of pyloric stenosis, it is surgical; if it turns out to be a case of diminished motility of the stomach, with a large pyloric orifice, it is usually medical, although it may be at any time surgical. Here the diagnostic methods of the laboratory help very materially in clearing that up. A mistake has been made in the past in depending on chemical methods and in keeping patients for a long time under observation, when finally the chemical results were practically of no value.

As to palliative surgical treatment, he has had some experience with patients suffering from cancer of the stomach. He has had many patients on whom gastroenterostomy has been performed. He has seen those patients live for more than a year after that operation; they have been relieved of stagnation; they have been made comfortable; they have gained greatly in weight, in general nutrition, and were happy for the time being. Right here he thinks the medical man has something to say, for the surgeon, after he has performed gastroenterostomy, does not take care of the patient. Medical men have to ease those patients down to the grave. The essayist, he said, has thrown much light on palliative operations, particularly pylorotomy, with removal of as many secondarily infected glands as possible. With this form of operation, as done by the essayist, drainage is established and continues until the death of the patient. Life is thereby longer prolonged than it is by a gastroenterostomy. He is willing to advise his patients to have an exploratory laparotomy made in doubtful cases; and yet one of the greatest surgeons of this city has said to him more than once that a laparotomy for diagnostic purposes should never be performed. In view of the fact that the technique of the operation for cancer of the stomach has been improved so much, so that the mortality, according to Dr. Mayo's figures, is now less than 10 per cent., physicians can turn over their patients to surgeons without the danger of having them killed on the table. A great deal, however, depends on who does the operation.

DR. CARL BECK stated that we have heretofore relied on European authorities, refraining from radical procedures for the removal of cancer of the stomach, and that we have sacrificed too many patients by doing palliative rather than radical operations. This is the first time we have had a report of a large number of cases from an American surgeon, based on true surgical and pathologic knowledge, with authoritative statistics, which can not be questioned, where gastrectomy has been shown to be preferable to any palliative procedure. He has had the opportunity of observing a patient in whom he did a radical operation on the stomach for carcinoma about

five years ago. He has had to do a secondary operation for carcinoma on the same patient in a different region, and during this second operation he examined carefully the stomach region and found it normal. The patient is now well.

Dr. Mayo said he feels confident that the near future will reveal methods of making diagnoses in these cases more easily than can be done now, and that as a consequence a considerable percentage of patients will be sent to surgeons much earlier for operation. The favorable cases of cancer of the stomach he has had to operate on, to a large extent were operated on at the time of ulcer, but in which true cancer was found. It was these early cases that led him to take more and more interest in the surgical side of the subject. Dr. Mayo disclaims any superior knowledge or skill in connection with the operation. He has seen the operation performed in many places in this country and abroad, and he does not believe there is anything in the statements that have been made from time to time crediting him with originality in this regard. He has not claimed any part of the operation as it is developed to-day. True, he has picked up little points here and there in the way of technique and put them together.

Lastly, he said we can not always make a pathologic diagnosis, and he thinks any man who says that we should not operate without a pathologic diagnosis is in error. He does not see how it can be otherwise, because a patient may have the appearance of cancer, when on making a purely exploratory operation there may be found an ulcerated mass or a well-formed tumor. This patient may present cachexia, loss of hydrochloric acid, etc., in which the surgeon may be confident before operation that he is dealing with carcinoma. Fifteen such cases he eliminated from his statistics, because pathologically, as shown by the microscope, they proved to be ulcer rather than carcinoma. Surgeons must occasionally do operations on cases in which the pathology is not clear before they operate; it is not even clear at the operating table, yet there is a condition present which can be relieved surgically.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns.]

Infantile Eczema.

In an abstract in the *Amer. Jour. of the Med. Sciences*, G. Clenet regards infantile eczema as a form of autointoxication, with the origin in the gastrointestinal tract. The first indication, therefore, according to this author, is to attempt to regulate the condition of the stomach and intestines by regular feeding, if the child is breast-fed, and by properly modified milk, if the child is bottle-fed. In cases of older children the diet should consist chiefly of milk, with a limited amount of eggs and vegetables. If any meat is given at all, it should be white meat preferably. Coffee, tea and alcohol should be entirely discarded. When there are arthritic tendencies, alkalies should be administered in these cases, and when there is a scrofulous condition cod-liver oil, iron or calcium glycerophosphate is recommended, and in children over 5 years of age, in whom the eczema is of a sluggish nature, arsenic may be administered. In those cases in which the dietetic and internal treatment do not suffice, local applications become necessary. The skin must be prepared aseptically by means of a mild non-irritating antiseptic, or by simply washing the affected parts with sterilized water. If crusts are present, Clenet recommends that they be loosened by the application of a poultice of potato starch, followed by an antiseptic powder. In cases of eczema of the scalp, sterile oil containing a small amount of salicylic acid is advisable. General bathing is contraindicated. As ointments he recommends those containing salicylic acid, sulphur, tar, or oil of cade. In some cases the dressings of silver nitrate are of service, followed by the use of

tar or salicylic ointment. In the most stubborn cases weak pastes of pyrogallic acid may be employed.

Treatment of Tapeworm.

Dr. S. L. Spier, in the *Yale Med. Jour.*, recommends in the treatment of tapeworm the use of pomegranate as preferable to male fern. He recommends that a decoction of the pomegranate bark freshly prepared be employed. Sixty grams of the finely powdered bark are placed in about 500 c.c. of water and allowed to simmer down to about 300 c.c. The patient may be placed on his usual diet on the day preceding the employment of the teniafuge, with the exception of the evening meal, which should be omitted or consist only of bread and milk. On the same evening he recommends the administration of a mild cathartic, such as compound licorice powder or the compound cathartic pill, on retiring. As soon as there is a free movement of the bowels the next morning, about one-half of the decoction (150 c.c.) should be given the patient, followed in fifteen minutes by a cup of hot black coffee, keeping the patient in bed, flat on his back. It is noted that the decoction easily produces nausea and, therefore, he recommends the sucking of lemons or the application of cold cloths about the neck to prevent this occurring. In about half an hour the remaining portion of the decoction of pomegranate may be given, followed in an hour or so by a large dose of Epsom salts or magnesium citrate. When the parasite starts to make its exit it may be found necessary to introduce a pint of warm saline solution into the bowel in order to assist in its expulsion. In unsuccessful attempts with this method after the lapse of six or eight weeks, when the parasite will have developed sufficiently, he recommends the administration of 150 c.c. of the pomegranate decoction, to which is added one or two drops of croton oil, when the most tenacious tapeworm will usually be dislodged. [In the administration of croton oil one must be certain of the patient's physical condition, especially as to the condition of the arteries and the heart, on account of the violent purging which this preparation is liable to produce in some cases.]

Liquor Ammonii Acetatis.

As a reliable diaphoretic and diuretic, Beasley recommends liquor ammonii acetatis in the following combinations:

As a diaphoretic in a simple cold:

R. Liq. ammonii acetatis.....	3ii	8
Tinct. aconiti.....	m. ii	12
Vini ipecacuanhæ.....	m. v	30
Aq. chloroformi q. s. ad.....	3i	30

M. Sig.: To be taken at one dose. Or:

R. Liq. ammonii acetatis.....	3iii	12
Syr. toluani.....	3ss	2
Aq. camphoræ q. s. ad.....	3i	30

M. Sig.: At one dose, diluted in water, and taken at bedtime.

In cases of acute rheumatism the following combination is recommended:

R. Liq. ammon. acetatis.....	3iii	12
Vini antimonii.....		1
Tinct. opii, āā.....	m. xv	1
Aq. camphoræ q. s. ad.....	3i	30

M. Sig.: At one draught, to be taken at bedtime.

[The amount of opium must be regulated to suit the individual case.]

In cases of bronchitis the following combination is advised:

R. Liq. ammon. acetatis.....	3iss	6
Spts. etheris nitrosi.....		1
Vini antimonialis, āā.....	m. xv	1
Syr. toluani.....	3ss	2
Mist. amygdalæ.....	3ii	8
Aque camphoræ q. s. ad.....	3i	30

M. Et. mistura. Sig.: One such dose to be taken every four hours.

In cases of acute nephritis the following is useful:

R. Liq. ammon. acetatis.....	3ii	8
Ammon. benzoatis.....	gr. x	65
Tinct. hyoscyami.....	3ss	2
Decoct. squarrii q. s. ad.....	3i	30

M. Sig.: One-half the amount taken in a little water and repeated in four hours.

The Administration of Mercury in Syphilis.

In outlining the treatment for syphilis, Otto Lerch, in *Amer. Med.*, recommends that the ulcer be extirpated to modify the general infection, and perhaps in some cases to prevent it entirely. After the appearance of constitutional symptoms, such as enlargements of the glands, skin eruptions, and so forth, he recommends that the mercurial treatment be commenced. It may be given by inunction in doses ranging from grains xlv to ʒii (3.00 to 8.00), of the blue ointment in each twenty-four hours. The patient should be instructed, according to this author, to divide the amount into two equal parts, using one part for each leg over the inside, and applying it with vigorous massage. He emphasizes the importance of rubbing for fifteen minutes over each side to cause the absorption, controlling the time by the watch, as the process is very tedious and the patient is too often liable to shorten the time. The following day the process should be repeated over the inside of the thighs in a similar manner, and the third day the inside of the arms; the fourth day the chest and abdomen; the fifth day the back may be similarly treated, and on the sixth day a full warm bath should be administered for cleansing purposes.

It is recommended that the patients use this inunction just before retiring, especially in the winter time, to prevent colds. Thirty inunctions generally constitute a full treatment.

In some cases he recommends that the unguentum belladonnae be added to the mercurial ointment to make it more pliable, and for its action on the salivary glands. The signs that the treatment is bearing good results are that the patient feels better and gains in weight. If a mercurial eczema should occur, as may be the case in some instances, the inunctions may have to be discontinued for a few days, and the eruption treated with the paste of zinc oxid. The treatment may have to be repeated for at least two years, giving one treatment every six months. Iodin in some form is a necessary adjunct to effective cure. The mercurial treatment may be alternated with the iodid medication, separated by short intervals.

Anal Fissure.

T. Chittenden Hill, in an article in the *Boston Med. and Surg. Jour.*, recommends as a palliative treatment in uncomplicated cases of anal fissure, in which the ulcer is shallow and the sphincters have not become hypertrophied and spasmodic, that a palliative course of treatment be tried and is usually effective. Careful attention must be given to diet and to regulation of the bowels. An ounce of olive oil must be given by the bowel at night, and the patient instructed to retain it until morning. This will produce both a local beneficial effect and will secure a soft movement of the bowels. Next in importance in the treatment is the necessity of observing strict cleanliness by local bathing night and morning with hot water. The parts should afterward be dried with a piece of sterilized gauze and a pad of the same material applied, and kept in position by means of a T bandage. Nitrate of silver in various strengths, even to the use of a pure stick, may be of value in these cases, as it acts by destroying the unhealthy granulations and the exposed nerve endings, as well as affording a protective covering by means of the formation of an albuminate of silver. The author recommends, however, the application of pure ichthyol to the fissure by means of a cotton swab two or three times a week, as of much greater value than nitrate of silver. (Cohnheim, of Berlin, states that he uses ichthyol locally, together with the olive oil treatment in all such cases, with great benefit.) This preparation locally allays the pain and it does not require but few applications to produce the desired effect. Whether using the nitrate of silver or ichthyol, it is probably best first to anesthetize the fissure by means of a local application of a strong solution of cocaine (10 per cent.). When these patients are discharged they should be instructed that if their constipation is not attended to and the parts are not kept clean, their trouble is very liable to recur. In those cases in which palliative treatment does not produce the proper response, or in which there is much hypertrophy and spasm of the external sphincter, the operative treatment is indicated. The operative procedures, as recommended by this writer, are stretching of the sphincters under general anesthesia, or a complete or partial division of the external sphincter under local anesthesia.

Medicolegal

Unregistered Practitioners Must Get Certificates.

The Supreme Court of Michigan says that in the case of *Hooper vs. Batdorff* attention was called to the fact that the act of 1899 required all persons engaged in or who wished to begin the practice of medicine and surgery to make application for a certificate, while the amendatory act of 1903 omits the former class, thus apparently limiting the laws to cases of beginners in practice. But the court thinks this inconsistent with the legislation on the subject, which began as early as 1883. It says that, considering the several acts, it is reasonable to believe that in 1903 the legislature took it for granted that practitioners then engaged in business had complied with the law of 1899, and that it was not the design to compel them to make application again. The court can not believe that it deliberately intended to offer a premium to law breakers, which is the effect of the first stated contention. It is more reasonable to say that a man practicing medicine in violation of law prior to the taking effect of the act of 1903 is a beginner for the purpose of making such application, not being already a lawful practitioner.

Temporary Certificates Abolished.

The Supreme Court of Nevada holds, in the case of *State vs. Lee*, that that portion of the act of 1899 providing for the issuance of temporary certificates of the secretary of the State Board of Medical Examiners has no longer any force as a part of the law of that state regulating the practice of medicine and surgery. It was argued that for several reasons there had been no repeal of the 1899 provision by the act of 1905. But, taking the act of 1905 as a whole, the court thinks it clearly manifest that it was the intention of the legislature to provide that no one should be permitted to practice medicine, surgery or obstetrics in the state, except after obtaining a license so to do from the State Board of Medical Examiners. Lastly, it says that it was argued that, as only two regular meetings of the board are provided for per annum, a construction of the statute as here given would impose a great hardship on those seeking to enter the practice between such regular meetings, and to impute such intention to the legislature would be unfair to that body. Doubtless the legislature in the passage of the act of 1905 was considering the public good, rather than the convenience of private individuals; but the legislature also doubtless intended to obviate the inconvenience that applicants to practice might experience from being unable to longer obtain temporary certificates by the provision, not found in the act of 1899, permitting special meetings of the board to be held at the call of the president of the board on two weeks' published notice.

Walking Before Jury to Illustrate Injury.

The Supreme Court of Alabama says, in *Birmingham Railway, Light and Power Co. vs. Rutledge*, a personal injury case brought by the latter party, that it, of course, could not know precisely what figure the plaintiff put when told by his counsel and allowed by the trial court, against the defendant's objection, "to walk the best he could before the jury." It would be difficult, if not impossible, to reduce the result of that experiment intelligibly to paper, and no effort to that end was made. So this court was not advised whether he did "his best" in the way of walking, or, to the contrary, did his best in the way of impressing the jury that his powers of locomotion had been greatly impaired. Certainly there was temptation toward the latter course; and it would seem impracticable by any sort of "cross-exercise" so to say, to test the good faith of his gait. Ethically speaking, there was grave doubt whether this man's physical organism should have been exposed to this temptation and to the strain necessarily incident to yielding to it, if he did yield. But on legal principle the evidence was on the same plane as that afforded the jury by a view of his person in repose, or by having him stand before them to show that one leg was longer than the other, were the shortening or elongation of a leg the thing complained of, or by exposing an arm to the jury on invocation to do his best in bending it at the joints, the claim being that it was stiffened, and therefore

incapable of normal use, and the like; and this court is not prepared to say that the lower court erred in allowing this walking illustration of the plaintiff's alleged injuries.

Presumptions as to Sanity and Suicide.

The Court of Appeals of Kentucky says, in *Masonic Life Association vs. Pollard's Guardian*, that the law presumes every man to be sane until the contrary is shown. Likewise the law indulges a presumption against suicide as being unnatural and immoral. But presumptions of this nature are indulged necessarily in the absence of proof. When the evidence shows and the fact is that the act of suicide was committed when the person was in sound mind, no presumption whatever can be indulged. It ceases to be a presumption and becomes a proven fact. Where the dead body is discovered in the presence of the implement of death, and the surroundings are such as admit of the conclusion either that it was self-inflicted or not, or was intentionally done or not, the evidence being wholly circumstantial, then the presumption against suicide, that is, intentional self-destruction, applies. Where, however, there are eye-witnesses to the occurrence whose testimony establishes the fact to be that the act was intentional, that the person was in a normal condition of mind, that he was not insane, that the motive probably influencing his action was the fear of disgrace, or of punishment for some past act, about to be disclosed or which had been recently discovered, then it would be illogical and contrary to the judgment and observation of mankind to say that the act was to be presumed in law to have been unintentional or the result of that insanity which deprives the mind of its knowledge of the probable effect of the act on life. Again, the court says, that the law is that if the insured intentionally took his own life, at a time when his mind was so far gone as to render him unconscious that he was taking his life, the act will not be deemed his, but will be regarded in law as an accidental killing. The converse is equally true—that although his mind may have been deranged, still if he had mind enough to know that the act would probably result in his death, and if he inflicts it with that intention, it is his act in law.

Surgeon's Claim Not Excepted from Exemption Law.

The Second Appellate Division of the Supreme Court of New York says that the practical question presented in the case of *Taylor vs. Barker* was whether the plaintiff, whose claim was based on personal services rendered by a surgeon to the defendant's wife, was entitled to an execution against the wages or income of the defendant under the provisions of section 1391 of the code of civil procedure. The plaintiff claimed, and he supported his claim by a long line of authorities, that words of the statute, "where a judgment has been recovered wholly for necessities sold," was broad enough to cover the professional services of a surgeon rendered at the request of the defendant. But the difficulty was that, if it be conceded that these words might, under certain circumstances, cover this case, such construction was made impossible by that higher rule of statutory interpretation which commands the court to read the entire statute, and to give force and effect to the legislative intent. The language of the act is that "where a judgment has been recovered wholly for necessities sold, or work performed in a family as a domestic, or for services rendered for salary owing to an employe of the judgment debtor, and where an execution issued on said judgment has been returned wholly or partly unsatisfied, and where any wages," etc., "are due and owing to the judgment debtor," the court may afford the relief from the exemption law provided in the statute. Whatever might be spelled out of the words "necessaries sold" under other circumstances, it must be entirely plain that the legislature by using the words "or for work performed in a family as a domestic," etc., intended to limit the scope of the statute to goods and chattels of the kind known as "necessaries" and to the special kinds of service mentioned in the act. The rule is as old as the common law that the express mention of one thing implies the exclusion of another, and it can not be doubted that this rule should be applied in the present case in arriving at the legislative intent. Hence the question presented in this case must be answered in the negative.

- 7 Indications and Contraindications to the Use of the Obstetric Forceps. J. T. Schell, Philadelphia.

1. **Unconscious Value of Careful Clinical Examination of Patients.**—Bishop emphasizes the fact that the careful clinical examination of a patient, carried on while the judgment is suspended, gives the opportunity for the subconscious development of a valuable opinion. This is entirely lost when the investigation is curtailed in time or details, and when the premature judgment is allowed to be formed. Therefore, it is most important that in every case in which a physician seriously undertakes the treatment, to make a very complete investigation into the history, the physical signs, and the laboratory findings, and, only after collecting these, to form a judgment as to the best course of treatment for that particular patient. The physician who is to give the opinion should, so far as possible, keep his mind free from conclusions until his final opinion is given on the case. It is the subconscious mental activity that produces those results that are considered so valuable in all professional work.

2. **Transplantation of Veins and Organs.**—Carrel and Guthrie obtained the reversal of the circulation in the jugular vein, in the carotid artery, in the arteries and veins of a limb. Important anatomic changes of a transplanted venous wall soon occur under the stimulus of the increased pressure. The thigh of a dog was completely amputated and afterward replanted by suturing the vessels, the nerves, the bones, the muscles, the aponeuroses and the skin. The pulsations of the popliteal and the posterior tibial arteries immediately became normal, and the femoral vein filled with dark blood. A kidney was extirpated and transplanted by anastomosis of the renal artery to the carotid artery, of the renal vein to the jugular, and the ureter was made to open into the lumen of the esophagus. On the third day after the operation the kidney was directly examined. Its circulation was found normal. A good excretion of urine was going on. The thyroid gland was extirpated and replanted with reversal of the circulation. On the ninety-fourth day after the operation, the gland was found to have a good circulation.

8. **Essentials of Successful Roentgen Ray Therapy.**—Leonard says that the Roentgen ray is a complex agent, produced by complicated apparatus, having varying qualities that must be adapted to the individual morbid process. Not only must the quality of the ray be adapted, but also its manner of application, so that its effective energy will be absorbed in the diseased area wherever situated in the body. It is so powerful an agent that it can do severe injury rather than good; so varied in its effects that timidity in its application will make it stimulate rather than retard the disease; so different in its qualities that it can be applied for long periods without producing benefit, if the quality appropriate to the lesion is not employed. Sound clinical judgment must determine the qual-

ity = 40% to be used according to physiologic action required. Treatment must be carried forward with energy and vigor, especially in the treatment of malignant disease. This is essential to success, and to do it the operator must often approach close to the point where healthy tissue is devitalized, for in no other way can the energy of growth of the malignant cells be injured and their absorption secured. The effect produced on normal tissue, i. e., the skin, is the guide. That effect must be so severe as to threaten its vitality, if underlying malignant disease is to be influenced. Very frequently in treating malignant disease an erythema or even a so-called burn are produced. Although it is necessary to push treatment in some cases to a point where a slight burn is produced, it should not be understood that a severe burn is necessary, or that when it is produced with proper therapeutic dosage it is of slight moment compared with the result obtained.

9. **Bacteriologic Study of Cerebrospinal Meningitis.**—According to Robinson and Goodwin, in the first week of the disease the meningococcus is present in the nasal mucus in fully half the cases; later in the disease it is found in a smaller fraction of cases. It also occurs in the nasal secretion of individuals who are in close contact with cases of cerebrospinal meningitis. In their series this occurred in about 10 per cent. of those examined. The disease seems distinctly communicable in the sense that the organism is transmitted from the nasal secretion of one person to another. The transmission of the organism, however, is not synonymous with transmission of the disease. The susceptibility of the individual is an important factor in the development of the disease. It seems unlikely that infection is frequently due to trauma or the result of overexertion. Cerebrospinal meningitis in other animals seems to have no connection with the disease in man. The subject, however, has not been sufficiently worked out to admit of positive statements. There was no evidence to show that the disease is carried by vermin or insects. The disease in some epidemics affects mostly infants; in others, older children, and sometimes chiefly adults. The reason for this is not at all clear. The period of incubation seems to be short, from one to four days. There was no evidence of the occurrence of "dwelling infections."

19. Alkalinity of the Blood in Febrile Toxemia. P. W. D'Evelyn, San Francisco.

15. **Epilepsy; Strangest Disease.** Sprattling points out some of the remarkable features of this disease, such as its many types, uncertain etiology, and its occurrence at all ages and in all stations of society. He predicts that when we shall finally come fully to understand the necessity of treating the epileptic body and as an individual, as a preliminary step in the more specific treatment of his disease, and after we shall have sufficiently developed our laboratory methods, we will cure epilepsy as often as insanity is cured to day, that is, in from 25 to 50 per cent. of all cases. He also speaks of the advantages attending the colony treatment of the disease, and urges widespread support of the principles of the National Association for the Study of Epilepsy.

17. **Original Method for Study of Osteology.** Gifford presents a method of carving models of bones from block or plaster of Paris. It is intended to facilitate the study of osteology. A rectangular block of the material, whose dimensions equal those of the bone in question, is prepared, and on its six sides projections of the outline of the bone are drawn. The plaster is then whittled away in conformity with these lines, thus forming a rough approximation of the bone, which can then be more carefully finished as to detail.

19. **Alkalinity of the Blood in Febrile Toxemia.** D'Evelyn's

patient, on the fifth day of a severe pneumonic infection, went into collapse under conditions which seemed to indicate the presence of a fibrinous deposit in the right auricle extending into the adjacent ventricle. Mechanical respiration was maintained for a period of five hours while the medication consisted of three minims of liquor ammonia fortis, and five minims of a 10 per cent. solution of iodine, mixed just at the time of administration, and repeated at longer and longer intervals. Recovery took place, and the author ascribes it largely to the fact that the alteration in the alkalinity of the blood was recognized and corrected.

21. Municipal Control of Tuberculosis. E. O. Otis, Boston.
22. Two Cases of Anatomic Anomaly of the Large Intestine. S. Robinson, Boston.

20. **Muscle-Splitting Incision in Appendicitis.**—Crandall and Scannell discuss 75 consecutive cases in which this incision was employed and conclude that the incision through the right rectus, as well as that through the right lineasemilunaris, is undesirable, because (1) it is usually not over the appendix; (2) it is frequently internal to the abscess, therefore giving mechanically inefficient drainage; (3) it offers in cases drained a distinctly greater chance of hernia. The muscle-splitting or McBurney incision is desirable in all cases of appendicitis, unless an abscess is obviously pointing in a remote or unusual situation, because (1) it opens most often directly over the appendix; (2) it can be enlarged by prolonging the split in each muscle-plane to whatever extent is desirable; (3) it can be drained for a short or a long time without danger of hernia.

22. **Anomaly of Large Intestine.**—In the first case reported by Robinson the sigmoid flexure apparently originated at the splenic flexure because the descending colon had not become adherent posteriorly, thus rendering a differentiation between sigmoid and descending colon impossible. From the splenic flexure to the rectum the bowel was freely movable, much distended, and elongated, measuring five feet and six inches. The diameter of the bowel varied from 3½ to 7 inches. The last five or six inches of small intestine adjoining the cecum were adherent to the posterior abdominal wall in a line from the right sacro-iliac synchondrosis to the lower border of the right globe of the liver. The ileum at this portion had lost its posterior peritoneal covering and was consequently subperitoneal. Its position and peritoneal relations then corresponded roughly to those of the normal adult ascending colon. The cecum was found resting at the upper border of the iliac fossa on the iliac crest. It could be moved upward or inward as far as the adherent last portion of ileum would permit it. The ascending colon was very movable. The second case was one of movable cecum. The small intestine is free as in the normal adult. The posterior surface of the mesentery of the ascending colon, however, has not become adherent to the posterior abdominal wall. The ascending gut has consequently no anchorage, and the cecum and appendix can be placed artificially in any part of the abdomen. The descending colon and sigmoid flexure were correspondingly movable, and the mesentery of the entire intestinal tube was free, except for a common median posterior attachment like that of the primitive mesentery of the young embryo.

29. New Drainage Tube. S. H. Kanner, New York.

29. **New Drainage Tube.** The instrument devised by Kanner is made either of silver or gold and consists of a cannula, the

length of which must be varied with the thickness of the abdominal wall, the cannula being just long enough to enter the peritoneal cavity. The caliber may be varied according to the requirements of the case. Perforations in the side of the cannula help to insure drainage. A thin disc of metal fits against the abdominal wall. The tube is so made that a screw cap closes its outer end tightly. Whenever it is necessary, the screw cap is removed and the fluid drains off. In the intervals the abdominal plate is covered with zinc oxid adhesive plaster, which does not irritate the skin. The cannula is inserted with a trocar. The trocar is removed and the fluid rapidly drains through the cannula. The technic is exactly like that of an ordinary paracentesis performed under strictest surgical asepsis, except that the cannula is left, the screw cap applied, and the abdominal plate covered with zinc oxid adhesive plaster.

33. Gonorrheal Septicæmia and Endocarditis.—Thayer cites additional cases in support of his contention that an acute urethritis is by no means infrequently followed by an endocarditis, either of specific gonorrheal nature or due to secondary or mixed infections which have found their portal of entry in the urethritis or have settled later on the primarily infected valves. The last two cases seen by Thayer presented the usual features of an ulcerative endocarditis—irregular, intermittent fever, chills, progressive anemia, and nephritis—developing, on the one hand, in a case of acute gonorrhea with arthritis about five weeks after onset, and in the other during a demonstrable urethritis, which the patient, a colored man, denied. In both of these cases, with a pure aortic lesion, there was a well-marked, presystolic, rumbling murmur, suggestive of mitral involvement. In one of the cases, a diagnosis of mitral disease was made. Cultures made from the blood during life were positive in one case, negative in the other. In both cases pure cultures of the gonococcus were obtained at necropsy from the affected valves. The remaining case, which is regarded as of especial importance, is an instance of gonorrheal septicæmia, with continued fever of seven weeks' duration.

34. Intrapleural Lipoma.—Fitz believes that his case shows that subpleural lipomata may have a medical as well as a surgical interest. The patient, aged 34, always well, with the exception of a "typhopneumonia," was seized with a severe chill, followed by pain across the chest, aggravated on deep inspiration. There was a distressing cough, with rusty sputum and considerable dyspnea. The physical signs indicated consolidation of the left upper lobe. In the lower left axilla, corresponding to the region of the inferior third of the lower lobe of the lung, there were dullness on percussion and absence of respiratory and vocal sounds. The mid-axillary region was occupied by a wedge of normal resonance and respiratory sounds, with its apex in the vicinity of the left nipple. There were dullness, diminished fremitus, and feeble vocal and respiratory sounds in the left back between the angle of the

scapula and the spine. Numerous medium, moist râles were heard at the base of the left lung behind. The left border of cardiac dullness was four and three-quarter inches from the median line, and the right border of dullness was at the right sternal edge. The apex beat was audible in the fifth intercostal space four and one-half inches to the left of the median line. The heart sounds were regular, rapid, and distant, the second sound was strong at the apex. Adventitious sounds were not heard. There were 41,200 leucocytes per cubic millimeter and 80 per cent. of hemoglobin. During the subsequent four days the temperature fell from 104 to 101, near which latter point it persisted. In the same period of time the pulse fell from 145 to 100, near which rate it subsequently remained. The respiration at first was from 50 to 35, but after five days ranged from 25 to 30, until within two days of death, when it rapidly rose to 45. For a few days the patient was mildly delirious; the white count remained high; the signs of consolidation persisted, but on the fifth day the failure to improve and the faintness of the heart sounds suggested the possibility of an acute pericarditis. Attention was constantly directed to the pericardium, as well as to the lungs and pleura, in search of an explanation of the persistent elevation of temperature and the continued leucocytosis. On the twentieth day of the disease it was noted that the signs of consolidation continued in the left lung. The right border of cardiac dullness remained at the right sternal edge, the cardiohepatic angle was obliterated, and the heart sounds were faintly heard. The pulse became paradoxical. Although dullness persisted in the left back between the angle of the scapula and the spinal column, the vocal resonance and fremitus and the respiratory sounds were normal. Repeated tappings of the pericardium failed to give any result. Death occurred two weeks after entering the hospital. On opening the pericardium a large amount, probably 500 c.c., of yellowish, opaque fluid gushed forth. Attached to the pericardium on the left side and apparently continuous with the fat tissue of the superior mediastinum was a large mass of fat tissue of about the volume of a newborn child's head, divided by delicate connective-tissue septa into larger and smaller lobules. It evidently occupied the inferior and anterior portions of the left pleural cavity, the left lung behind and above it. The large amount of fat tissue was more or less adherent by fibrous adhesions to the diaphragm, to the pericardium, to the parietal pleura, and to the inferior lobe of the left lung. Portions of it were left in the body on removal of the thoracic viscera. So far as could be determined, the shape of the mass of fat tissue was more or less that of a pear, the small extremity being attached most firmly to the external surface of the pericardial sac along a line extending from the anterior mediastinum in the region of the pulmonary artery (where it seemed to be continuous with the fat tissue of the pericardium) downward on the left side toward the posterior mediastinum. The mass of fat tissue appeared to be covered in places by a thin, shiny layer resembling the pleura. The appearances in the section indicated a lobar pneumonia in which resolution had not been thoroughly established. The congenital origin of the lipoma was indicated by the accompanying hypoplasia of the lower lobe of the left lung.

38. Larynx in Typhoid.—From laryngoscopic observations of 360 typhoid fever cases Jackson concludes that serious and fatal lesions of the larynx are much more frequent than is realized. Death may occur from laryngeal stenosis without even the existence of a laryngeal lesion being suspected in the absence of laryngoscopy. If pain and hoarseness be depended on, a diagnosis will seldom be made. Pain is often masked by toxæmia. Cyanosis and dyspnea are rare, apnea is common. Unlike the complications of the exanthemata, ulcerative laryngitis complicating typhoid fever, in the likelihood of its occurrence, its course, and its termination, bears a close relation to the severity of the primary disease. The severity of the laryngeal lesion is in direct proportion to the toxæmia, pyrexia not being in itself a factor, but only an index of the toxæmia. Thrombosis of laryngeal vessels in the mucosa or deeper is probably the most frequent local initial lesion. Mixed pyogenic infections are the rule. Laryngeal lesions due to the

Bacillus typhi abdominalis are exceedingly rare. Prognosis as to life is good as considered apart from the general malady. Not only the life, but the laryngeal vocal and respiratory functions will be saved if a tracheotomy be done early. Death from laryngeal lesion means a death for want of an early tracheotomy. Prophylaxis consists in good ventilation, without draughts, sterile bedding, oral antiseptics, sterile food, and water. Potassium iodid, hydrargyrum biniodid, benzoïn inhalations, and oral antiseptics are the best remedies. Early tracheotomy under local (Schleich solution) anesthesia will effect a cure in almost every case.

41. Cause of Pulsations in Empyema.—While working on cross-sections of a body with pleurisy of the left side, the anatomic relationship of the organs suggested to Calvert an explanation for the pulsating empyema which, on analysis, seems to fulfill all the requirements. He says that the requirements are a firmly fixed pulsating organ; contact of the pleural wall with this pulsating organ; distention of the pleural sac with fluid, air, or solid material, and a collapsed condition of the lung. The first requirement is fulfilled by the thoracic aorta; the second, by the normal relationship of pleural wall to thoracic aorta; the third, by the presence of fluid, pus, or a combination of these with air in the pleural cavity; and the fourth, by the collapsed condition of the lung in pleurisy and empyema. In the normal thorax the pulsations of the aorta are absorbed by the easily compressible lung tissues, consequently are not transmitted. When the fluid is present in the left pleural cavity, the lung is partially or completely collapsed, depending on the amount of fluid. As the fluid increases, the thoracic walls and mediastinum are pushed outward from the cavity of the left pleura and the lung becomes more and more collapsed. Until the lung is completely collapsed it naturally contains more or less air; consequently it is compressible and capable of absorbing, or compensating for, the impulse of the aorta. In time, however, a point is reached when further to compress the lung a pressure sufficient to expand still more the thoracic wall, more especially the intercostal spaces, is required. The impulse of the aorta transmitted to the pleural effusion will further expand the intercostal spaces or pulsation of the intercostal spaces is present. The pressure in the pleural cavity is transmitted in all directions at right angles to the pleural walls; consequently the aorta is pushed to the right as far as the left intercostal arteries permit and against the vertebral column. The arterial wall expands in all directions. The artery being firmly fixed against the vertebral column and nearly half covered by the parietal pleura, which does not offer a resistance equal to that offered by the vertebral column and stretched left intercostal arteries, the aortic pulsations must be transmitted to the fluid in the pleural cavity. This pulsation of the effusion is transmitted equally in all directions and must be taken up by the elasticity of the mediastinal membranes, diaphragm, and thoracic wall and the compressibility of the lung. Of these structures, the one with the greatest elasticity will absorb the greatest portion of the impulse. As this pulsation is purely hydraulic in principle, the nature of the fluid in the pleural cavity is of little or no importance. Consequently, in pleural effusions pulsation is not a positive sign of empyema. In the literature only three cases of pulsating pleurisy are recorded.

46. Echinococcus Multilocularis.—According to Smith, every form of multilocular hydatid hitherto described is found in Australia and may occur in large numbers in animals from certain localities. A "tunneling" form in the liver not previously described is also found. The commonest form occurs

in all parts of the lungs and liver, and consists of a number of "graded" loculi communicating with one another and varying in size from 1 to 10 mm. or more in diameter, with ectocyst and endocyst continuous throughout the loculi, the small loculi being barren, the large fertile, and all inclosed in a common adventitious fibrous capsule, which, with the contained cyst, forms a tumor that can be fairly easily "shelled out" of the organ in which it is found. The calcified pearl tumor, or beaded chain of tumors, is found most commonly at the transverse fissure and near the notch of the liver. A great ramifying hydatid of the lung is described, measuring 2 mm. in diameter, including the capsule, which is undergoing calcification. A three or more locular hydatid of the liver is described, measuring 4 mm. in diameter, including the capsule, which is undergoing calcification. The changes in the tissues of the lung and liver consist of (a) round-cell infiltration; (b) proliferation of the epithelial and connective tissue elements; (c) formation of giant cells in two ways; (d) adenomatous new growth; (e) formation of fibrous capsule by proliferation of the cellular and fibrous tissues of the part of the organ in which the hydatid grows; (f) calcification. Investigation of pathologic changes which occur in the lung in the presence of worms shows that they consist of (a) infiltration, (b) proliferation of the epithelial and connective tissue elements, (c) giant-cell formation, (d) adenomatous new growth, (e) fibrosis, and (f) calcification, and are not distinguishable from those to be observed in the case of hydatid tumors. No satisfactory explanation has been given of why mechanical irritation of one part should cause overgrowth in a part where the irritation does not and can not act mechanically. Hydatid cysts develop in the lumen of the bronchi, and attain the size of a hen's egg or larger, a favorite spot being just beyond the point where the cartilaginous elements cease. This confirms Dr. Dougan Bird's theory that eggs of the tenia may reach the lungs direct by the air passages and there develop. There is a large amount of evidence to show that hydatids reach their positions of further development in the lungs, liver, and elsewhere by the lymphatics, portal vein, and arteries. The thickness and amount of calcification of the fibrous capsule bear no relation to the age, size, position, or mechanical irritation of the tumor. There is an intimate connection between the cuticle (ectocyst) and the adventitious fibrous capsule. In some instances a layer of cells between the two appears to add to the thickness of both. There is evidence that the outer as well as the inner surface of the cuticle is cellular and that both have similar functions. There is no evidence of any causal connection between hydatids and tuberculosis, although the two conditions are very often associated. Suppuration, in healthy animals, of hydatid cysts, if it occurs at all, is extremely rare. Calcification may affect the fibrous capsule, the laminated membrane, and the contents of the cyst, and may occur at any stage in the growth of the tumor. The theory that calcification is a process of degeneration due to the cutting off or diminution of the blood supply consequent on the increasing fibrosis of the capsule is disproved. Spontaneous cure is not uncommon and may occur in any organ of the body apart from any question of the presence of resisting structures. Multilocular hydatids are fertile at a very early stage of their existence. The worms often appear to have more slender necks than those in the unilocular cysts of the human subject. The multilocular form is not dependent on mechanical pressure. A false form may originate from unilocular cysts: (a) By two continuous cysts coalescing; (b) by constriction; (c) by ingrowth of the walls; (d) by pouching or evagination. A typical echinococcus multilocularis is multilocular from almost the earliest recognizable cystic stage, and can not, in the present state of our knowledge, be called merely a variety of any other form of hydatid.

49. Epilepsy Treated Successfully by Administration of Nuclein.—Dewey cites the case of an epileptic who was benefited remarkably by nuclein. The disease had existed for about 17 years. The convulsions were typical grand mal of rather severe grade. Because of an inoperable desmoid subserous growth of malignant character situated in the abdominal wall, the use of nuclein was begun in 1896. Hypodermic injections were given daily for about five weeks, in 20-minim doses, in-

creasing to 80 minims. The injections produced indurated lumps in the arms at the sites of injections, and some of these softened and were evacuated; they did not open spontaneously. After the formation of these masses the injections were discontinued and protomucin given internally, gr. v, t. i. d., for six weeks or two months. After a month it was noticed that the pain of the tumor and a coincident irritation of the bladder diminished. A slight reduction in size of the tumor was also discernible. Early in 1897 he had increased frequency of convulsions and return of pain in the hypogastrium, and was given bromids and chloral, gr. x, at night, with some improvement. In March, 1897, the 1 per cent. mucin solution was given (by the mouth) in doses of half a dram at bedtime for some weeks. There was some slight gradual improvement in all symptoms, both of epilepsy and tumor, and in May and June, 1897, the patient again took the hypodermic injections for five weeks, with some improvement in the general condition and no further appearance of indurated nodules, but the tumor was somewhat increased in size. In October, 1898, the patient seemed to be failing physically, and the tumor continued to give much pain. He could take little or no exercise, and mentally was impaired, forgetful, dull and depressed. In December, 1897, daily dram doses of mucin solution were given hypodermically for some weeks. The mucin injections were continued on into March, 1898. There was no abatement of the epileptic attacks, but the pain of the tumor was less and there was some retraction in size. In April and May, 1898, the patient took protomucin powder for eight weeks. The convulsions continued to occur at the rate of two or three every month till November, 1898. In October the patient ceased the use of all bromids or chloral. He seemed to show physical improvement, became more active mentally and stronger physically, and was able to take more exercise. From this time physical and mental improvement continued. These were, perhaps, attributable in part to cessation of all sedatives and bromids and to the systematic hydrotherapeutic treatment with massage, hygienic regulation of life, etc., at a sanitarium; but these measures scarcely accounted for the recession of the tumor, which from that time up to October, 1905, has ceased to cause any inconvenience. After Nov. 29, 1898, there was no seizure till Feb. 22, 1899—a longer interval of freedom than had occurred for several years. There was no further convulsion until May 6, 1899; another occurred May 25; then there were none until July 16, 1899. Since October, 1898, up to the present time, attacks have occurred about twice in each year. The epilepsy is not cured, but has undergone an unusual amelioration. In 84 months there were ninety attacks, and it is probable many occurred that were not recorded. From November, 1898, to the present month, another period of 84 months, there have been, as nearly as can be ascertained after careful inquiry of patient and his family and friends, fourteen attacks.

52. Bacteriology of the Puerperal Uterus.—In 50 consecutive women in whom the lochia was examined by Little immediately after labor and on the third and seventh days of the puerperium, the uterus was absolutely sterile in 92, 50, and 44 per cent. of the cases, respectively. Counting as negative the cases in which gonococci were present, the figures are 96, 72, and 67 per cent. The puerperium was normal in 40 and febrile in 10 cases. In the former, the percentages of absolute sterility were 92.5, 62.5, and 50 per cent., as compared with 90, 40, and 20 per cent. in the latter; or, counting as negative the gonor-

rhoeal cases, the figures 95, 85, and 70 per cent., and 100, 50, and 50 per cent., respectively. The results were considered as positive when bacteria were found only in smear preparations or only in cultures, as well as when present in both. It is probable, therefore, that a certain number of the positive results were due to contamination, and that the uterus is really sterile in a larger proportion of cases than is indicated by the figures. The streptococcus was found but once in the entire series, being present in a febrile case on the third day, but absent on the first and seventh days.

59. Extirpation of Fauical Tonsil.—The method which Todd has found most successful and now practices is as follows: In nearly all cases a general anesthetic is administered, and those operations performed under a local anesthetic are on adults or older children, who have good control of the throat. In such cases, the tonsil is anesthetized with a 10 per cent. solution of cocaine, the crypts being cleaned out, the cocaine is swabbed repeatedly into these holes after using a suprarenal preparation, as Todd has found that the contraction of the blood vessels helps to prevent the toxic effect of the cocaine. Even when cocaine is used, certain portions of this operation are apt to be painful. When the patient is under a general anesthetic the head is dropped over the end of the table, and the operator sits on a stool facing the patient's face, which is exactly upside down. Strong direct daylight is used, the mouth gag is inserted, the patient's tongue is held by an assistant standing at the side of the table, the tonsil is grasped with the tonsil forceps, and with tonsil knives the anterior pillar is dissected loose from the tonsil, care being taken not to injure the pillar, for it is from the pillars that most hemorrhages arise, and it is not desirable to injure these muscles if we would secure perfect results. With a pair of slightly curved scissors the tonsil is separated above and below, being all the time pulled out with the forceps, the forceps are then released and the Kratzmüller cold wire snare applied. After placing the loop over the tonsil, this is pulled out with the forceps again and well into the snare, an assistant aids further by exerting pressure from the outside on the neck, thus pushing the tonsil into the snare. By this time the tonsil is only attached by a pedicle, and by rapidly bringing the handles of the snare instrument together the wire is brought into the cannula, and the tonsil is thus peeled out. If the technic is perfect, the entire tonsil is enucleated, the back surface being smooth and covered with membrane. If a portion remains, it should be pulled into the snare and removed, but this should not be necessary if the operator has been careful. There is less hemorrhage than with the tonsillotomy or scissors. Todd says that, if the pillar is cut with the knife or scissors (an accident that need not occur), there may be bleeding, and if it is severe it may be stopped by ligating the pillar.

British Medical Journal.

December 26.

- 1 *Carcinoma Is a Parasitic Disease. H. T. Butlin.
- 2 *The Heredity of Insanity. A. R. Urquhart.
- 3 *Prognosis in Mental Diseases. R. Jones.
- 4 Postmortem Examinations Which Do Not Reveal the Cause of Death. F. J. Smith.

1. **Carcinoma Is a Parasitic Disease.**—Butlin insists that carcinoma is a parasitic disease, not in the limited sense in which this term is sometimes employed, as synonymous with infective, but in the larger and wider sense in which it should be employed, to express the fact of one organism living at the expense of another, each pursuing its otherwise separate and independent existence. He maintains that the carcinoma cell is an independent organism, like many a protozoan; that it lives a life which is wholly independent and proper to itself; and that it lives as a parasite in the body of the animal which is affected with carcinoma, deriving its nourishment from this host and doing nothing to repay the host for sustenance of which it robs him. The biology of the carcinoma cell is discussed at great length. Butlin urges that a careful study be made of the life history of this cell outside the body of the host, and with this end in view repeated attempts should be made to induce the parasite to thrive and to multiply under artificial conditions which will permit the study of every phase of its existence.

2. **Heredity of Insanity.**—During twenty-five years Urquhart has had 1,104 cases under his care, representing 886 patients; 623 of these individuals were hereditarily predisposed to insanity, eccentricity, neuroses, paralysis or alcoholism, while 394 had a distinctly insane heredity. During the last ten years 304 of 375 persons showed a neurotic and insane heredity, while the heredity of insanity occurred in 180 cases.

3. **Prognosis in Mental Diseases.**—Jones has taken the histories of 230 male patients whose fathers or mothers were known to have been insane. In 10 of these cases both parents were insane; 3 of the 10 patients died of general paralysis. Of the total 230 males the high proportion of 27.4 per cent. had previous attacks; 30 patients died from general paralysis, a proportion of 13 per cent., a slightly higher proportion than occurs in the admissions as a whole, and it is this seen that general paralysis not only may but does present a hereditary history of insanity. The number of deaths was 87, a proportion of 38 per cent., which is abnormally high, and demonstrates that hereditary insanity tends to extinction. The recovery rate is the same, namely, 38 per cent., which is also higher than among the general admissions. Of those who recovered 13.8 per cent. relapsed during the twelve years, again a slightly higher ratio than occurs among the total recovered of all classes (13.2 per cent.). These facts tend to show that patients with a hereditary neurosis (taking an attack of insanity to indicate this) recover quicker, that they relapse sooner, and that the others die sooner. This is epigrammatically foreshadowed by a high authority, who states that heredi-

tary cases are easier broken down but are easier reset, and that as to recovery, "if a man is to become mad, he had better have a mad ancestry," meaning that the prognosis as to recovery is better when a hereditary taint is recorded.

7. **Nervous Manifestations of Acute Rheumatism.**—Poynton and Payne believe that eventually rheumatic chorea will prove to be a local infection of the nervous system and that most of its symptoms are the result of a slight meningo-encephalitis or possibly meningo-mylitis. Their reasons for this belief are: 1. They have isolated and cultivated the diplococci from the cerebrospinal fluid in 4 cases of fatal rheumatism, in 3 of which there was chorea at the time of death. 2. They have produced twitching movements, arthritis, endocarditis, and pericarditis by intravenous injections of the diplococcus into rabbits. 3. They have demonstrated the presence of diplococci three times in the cerebral pia mater and once in the brain from cases of chorea. 4. They have demonstrated them in the brain and pia mater of the rabbit that had shown the twitching movements. They report the case of a boy 13 years old who was suffering from arthritis of the ankles and knees. The family history showed that the boy's father had suffered from rheumatic fever, but the patient himself, except for an attack of measles and an operation for adenoids, had enjoyed excellent health. He appeared to be suffering from a very ordinary attack of rheumatic fever, which yielded to rest and salicylate of sodium within four days. Seventeen days later, without any apparent cause, the temperature rose to 102.4; the boy complained of headache and vomited. On the second day following he became unconscious, with fixed, dilated pupils and general muscular rigidity, alternating with flaccidity. The axillary temperature was 102.4; the rectal temperature was 106.4. The boy died comatose the next day. The authors consider this a case of rheumatic meningitis, the clinical diagnosis being confirmed at the autopsy. They believe that these nervous lesions are comparable to rheumatic lesions of other organs.

9. **Tuberculin in Tuberculosis of Urinary System.**—Pardoe used the tuberculin TR, subjecting it to a temperature of 60 C. for one hour. In the greater number of his cases very little local effect was noted at the site of the injection; in 2 cases a decided reaction followed. The tuberculin was given hypodermically with a sterilized syringe, beginning with a dose of 1.500 mg. and increasing this dose every other day until a definite reaction was obtained. The dose was then reduced to that quantity which apparently caused no reaction, and was then given steadily once a week for long periods. During the progress of the treatment the patient's weight and temperature were carefully noted. A cystoscopic examination was made from time to time. Of 21 patients so treated 5 are apparently cured, 4 show a very marked improvement, 6 show no improvement, and 6 succumbed. In one of these Pardoe thinks the tuberculin was the direct cause of death. He says that the more circumscribed the infection the better are the results, in not one case in which the cystoscope showed diffuse infection was much benefit noted. The cases of apparent cure occurred when only a small amount of bladder surface appeared to be involved. He inclines to the belief that for vesical tuberculosis tuberculin is the best remedy at our disposal.

Glasgow Medical Journal. December.

- 11 *Mode of Spread of Breast Cancer in Relation to Its Operative Treatment. W. S. Handley.
- 12 The Ophthalmoscope in General Medicine. A. M. Ramsay.

11. **Cancer of the Breast.**—According to Handley, cancer of the breast spreads primarily in the paresthesia along the deep fascia, and not along the skin; hence it appears to be unrec-

sary in all but exceptional cases to remove such a large area of skin as to prevent complete suturing of the wound. He thinks that as a rule it suffices to remove a circular area of skin centered on the primary growth and from 4 to 5 inches in diameter. The incision he makes consists of three parts: 1. A ring incision, as practiced by Mitchell Banks, from 4 to 5 inches in diameter, accurately centered on the growth and surrounding it at a safe distance, slightly tailing off into part 2 above, and into part 3 below. 2. A curvilinear incision for giving access to the axilla. The axilla is opened by turning forward a flap consisting of skin and a thin layer of subcutaneous fat, whose base lies along the anterior maxillary fold. The axillary incision begins at the lower edge of the pectoralis major, close to its insertion. It ends, also at the lower edge of the pectoralis major, by joining the annular incision. It crosses the base of the axilla, and marks out an almost semi-circular flap of skin, whose convexity reaches back nearly to the edge of the latissimus dorsi. It affords perfect access to the axilla and good drainage afterward. 3. A linear incision coming off from the lower and inner part of the annular incision and passing downward for about 2 inches along the linea alba. Its object is to give access for the removal of the deep fascia over the upper part of the abdominal wall. Without it this important step in the operation can not be properly carried out. Handley says that the most convenient way of suturing this incision must be a matter of trial in each case, according to the precise situation of the growth in the breast. Usually, perhaps it will be best sutured in a triadial form. It will, however, never result in a rectilinear scar, nor in one lying along the anterior axillary fold, nor does it remove any presumably healthy skin. It, therefore, avoids the faults of the usual incision without, as Handley believes, any corresponding disadvantages. The pull of the arm being at right angles to the direction of the scar, the cicatrix more readily becomes mobile on the chest. During this process the scar may be stretched to a width of nearly an inch.

18. Case of Landry's Paralysis. A. S. Joske.
16. Extroversion of Bladder. Newland reports a successful case of extraperitoneal implantation of the ureters in extroversion of the bladder which had existed since birth. The patient was 7 years of age. At the age of 3 a plastic operation had twice been unsuccessfully performed. On examination a pyriform area of bright red mucous membrane was to be seen in the pubic region. The stalk lay downward and was formed by the penis, which was in a state of complete epispadias. Above and at the sides the junction of skin and mucous membrane was well defined. The latter showed a scarred condition due to the previous plastic operations. The exposed surface of the bladder ended below in the cleft urethra, in the proximal portion of which the vera montium could be recognized. A transverse sulcus, due to the folding of the urethral on the vesical mucous membrane, existed. When this was opened out by gently drawing the penis downward, the vera montium and urethral orifices were more distinctly exposed. The latter lay at the summits of two papilla, from which urine gushed forth intermittently, but seldom simultaneously. There was no ulceration of the vesical mucous membrane nor irritation of the surrounding skin. The cleft prepuce was very large. The scrotum was well developed but bifid. The testicles were incompletely descended. They lay below the external ring and could be pushed into the scrotum. No hernia existed. The pubic bones were widely separated. The gap could be felt distinctly. The inner surface of the thighs, instead of meeting at a narrow angle at the perineum, were separated by a wide interval. The anus was dilated and the rectum washed out with saline solution. The vesical ends of the ureters were then freed according to the method employed by Peters, A No. 3

Jacques catheter was passed into each ureter for about 2 inches and fixed to the urethral papilla, the one with fine silk the other with a fine catgut stitch. A circular incision of as great extent as possible was then made through the mucous membrane around each papilla. This was deepened until the bladder wall was completely cut through. The separation of the ureter from the loose cellular tissue, in which it lay along the wall of the pelvis, was easily effected. Each ureter was exposed for from 1½ to 2 inches. With the left forefinger in the rectum and the right in the suprapubic wound, the anterior and lateral walls of the rectum were defined. A Listers sinus forceps was passed into the rectum and its fine point thrust through the lateral wall about 1½ inches above the anus. The small wound was dilated by opening the blades of the forceps. The catheter in each ureter was grasped by the sinus forceps and drawn through the wound in the lateral wall of the rectum on the corresponding side. The ureter followed the course of the catheter, the rosette of vesical mucous membrane passing through the wound in the rectum much as a button passes through a buttonhole. The catheter in the left ureter was forthwith removed. The rosette on the right side was not a large one, and it seemed better to leave the catheter in the ureter. The remainder of the vesical mucous membrane was not interfered with. The wound left by the transplantation of the ureters was gently packed with iodoform gauze. The free end of the catheter in the ureter was passed into a bottle containing boracic lotion. The operation, though tedious, was well borne, and the patient did not suffer from shock. Two days after the operation the patient retained his urine from two to three hours during the day, but was troubled with incontinence at night. He gradually acquired more and more control over the flow of urine until at the end of the month he was able to remain dry all day and only occasionally wet his bed at night. Six months later the remaining mucous membrane of the bladder was dissected away. The raw surface was diminished in size by the insertion of transverse Halstead sutures of catgut. The skin was then freed all around, and extensively undermined. As the skin still could not be sutured across the raw surface without tension, a curved incision, with the convexity upward and outward, was made on each side from the upper limit of the raw surface left by the ablation of the vesical mucous membrane to the groin. The wound, when closed, presented a triadial appearance. At the same time an attempt was made to close the proximal portion of the urethra. An incision was made along the junction of skin and mucous membrane. A flap of the latter was dissected up on each side and sutured the one to the other. The skin was undermined and sutured over the urethral mucous membrane. The whole wound healed well, with the exception of the small portion lying over the urethra. A month later another attempt was made to establish a urethral canal. On this occasion the penile urethra was treated as well. The mucous membrane was dissected up on each side and sutured. The skin was joined over this. There was considerable tension, and union again failed. Two months later the whole of the urethral mucous membrane was dissected away. An incision was made through the prepuce at its junction with the glans, and it was then stripped from the under surface of the penis. A large flap of skin was thus obtained. It was next buttonholed, and the glans penis passed through the opening. The flap was then sutured along the dorsum of the penis. On this occasion the wound healed well and the patient was able to return home.

19. Arsenic Iodid in Treatment of Scrofula.—Saint-Philippe has treated 200 children during the last decade with arsenic iodid and has found it very valuable in scrofula and scrofulo-tuberculosis. The hypertrophied glandular apparatus is in a

condition of functional hyperactivity while at the same time there are signs of nutritional disturbances. The iodo-arsenical medication meets both these indications. He orders from 10 to 40 drops of a 1 per cent. solution of arsenic iodid, morning and evening.

Semaine Médicale, Paris.

23 (XXV, No. 50.) *Hysteric Blindness.—La cécité hystérique. Dieulafoy.

23. **Hysteric Blindness.**—In one of the two cases described the blindness was the only apparent manifestation of the hysteria. The patient was a young man of 25, a mason. On his way home from work he suddenly became blind and could not remember the names of the streets where he wanted to go. He was supposed to be drunk, and was taken to the station and then to the hospital. There was a history of well treated syphilis three years before after an unfortunate love affair. He recovered his sight in about two weeks under application of a magnet to the side, bread pills and suggestion, but the blindness recurred six weeks later and again persisted for two weeks. The second patient was a woman of 44, long known to be hysteric, and completely blind and hemiplegic during the last ten months. Vomiting and intense headache had been noted as the blindness first came on. Dieulafoy has collected 59 cases of hysteric blindness including these which he reports. In 5 patients the blindness was the sole manifestation of the hysteria, appearing in apparently healthy persons. The blindness is absolute, but the pupil reflex is retained. Contracture of certain muscles has been frequently noted, especially the muscles of and around the eye. The media of the eye were found normal. The duration of hysteric blindness may be weeks or months, but no case is known in which vision was not finally recovered except in the above case still under observation. Traumatism may cause hysteric blindness which may not develop until weeks or months after the accident. It is liable to persist indefinitely, although in some cases it vanished permanently in a few weeks or months. Severe headache generally preceded the onset of the blindness in all cases.

26 *Laws of Mechanics and Hydrostatic Pressure as Basis for New Points of View in Regard to Origin and Treatment of Functional Stomach Affections.—Gesetze der Mechanik, etc. Agéron (Hamburg).

24. **Affections of the Esophagus.**—Ehrlich relates the particulars of 19 cases to illustrate various points in the diagnosis or treatment of affections of the esophagus. In 2 cases the esophagoscope revealed a cancer in the cardia before it was palpable or had induced cachexia, or while total extirpation was still possible. In one case, a man of 43 complained for three weeks of a difficulty in swallowing. Two brothers had died from cancer of the esophagus. Nothing abnormal could be discovered with the esophagoscope, but the disturbances continued and finally a ring-shaped cancer became apparent in the esophagus, completely closing the lumen. A Kader fistula into the stomach answered its purpose perfectly for nearly a year, when the patient succumbed to metastasis in the lungs. In introducing a laminaria tent Ehrlich bores a hole in one end about 1 cm. deep and inserts a fine sound in the hole, winding the stout thread from the tent around the handle. This holds the tent firm, while it does not interfere with vision as much as when the tent is held with forceps.

26. **Treatment of Stomach Troubles.**—Ageron's work is based on more than 5,000 examinations of the stomach content and conditions. They appear to show that the standards for gastric digestion and evacuation of the stomach generally accepted are incorrect. A test meal of 250 gm. tea, 100 gm. bread and butter and one egg is totally evacuated in two hours, while six are required for the evacuation of a meal of soup, 250 gm. meat with potato, vegetable and preserves, under normal conditions, the individual sitting or standing. Normal conditions presuppose an elastic counter pressure on the part of the walls of the stomach to the pressure of the fluids in the stomach. If for

any reason this elastic counter pressure is defective, the weight of the ingested fluids forces down the stomach and it sags below the horizontal line of the umbilicus, the surface of the fluids being so low down that the weak muscular contractions of the stomach walls fail to drive the fluid toward the pylorus. Evacuation, consequently, is delayed and the food is not properly expelled as it should be to ensure normal intestinal digestion by the due interaction of the digestive reflexes at the proper time. By lying down, especially if the individual lies on the right side and with the pelvis raised, the food in the stomach is brought up to the pylorus, and evacuation proceeds easily and rapidly. The benefits of "mast cures," that is, rest in bed with forced feeding, are due to the horizontal position assumed and the consequent relief of the sagging stomach. The characteristic element of a physiologic stomach is the tension of the stomach wall after ingestion of food and the concentric counter-pressure thus exerted. The motor sufficiency of the stomach is dependent on the degree of tension and the intensity of the counter-pressure. The large majority of stomach disturbances are merely the result of a permanent disproportion between the weighing down of the stomach walls by fluid or other food, overhastily ingested, that is, taken in too brief a time, and the physically possible counter-pressure on the part of the walls. Agéron adds that the evidence of dynamic disturbances in the stomach can be obtained with certainty only by repeated test risings. The sagging of the fundus and greater curvature causes a vicious circle, reducing constantly more and more the power of concentric contraction of the stomach walls. Pregnancy will sometimes cure by lifting up the stomach and thus bringing the contents nearer the pylorus, so that they can be readily evacuated. Horizontal rest cures are indicated in all cases of motor gastric disturbances dependent on a reduction in the power of concentric counter-pressure in the muscles of the walls of the stomach. In conclusion he emphasizes the point that the positive or negative result of the horizontal rest cure may be accepted as a criterion for or against the necessity for operative treatment of protracted gastric affections with severe motor disturbances.

30 *Zum Kapitel der nervösen Blasenstörungen (bladder disturbances). J. Vogel.

30. **Nervous Bladder Disturbances.**—Vogel reviews considerable literature on this subject, his general conclusion being that some organic cause for the bladder disturbance can almost always be found on diligent search. The nerve connections between the abdominal organs are remarkably close and complex, which may render difficult the differentiation of the source of the trouble. He mentions examples and also cites cases of true neuroses. They are especially frequent among public speakers and actors, who dread to be disturbed by desires to urinate during their appearance in public. He mentions the case of a clergyman who always catheterized himself before his sermon to make sure that his bladder was empty. Peculiar bladder disturbances are sometimes noted in patients in whom the cystoscope reveals extreme hypertrophy of the bladder with the muscular bundles very apparent ("Balkenblase"). Some of these patients present indications of incipient tabes. There are no true bladder crises, but merely occasional sensations of oppression and discomfort in the bladder region, and micturition may be difficult. There are never increased desires to urinate. The disturbance in the central nervous system causes disturbance in the bladder functions which in time induce severe anatomic changes in the bladder. A disturbance in some part of the urogenital system may cause pains to radiate to some other part of the system, as for instance, the pains radiating to the glans penis in case of stone in the bladder, or radiating to the bladder from the prostate in case of chronic inflammation of the latter. The bladder pains are liable to

persist in the trouble in the prostate has subsided. Residual urine has been noted in young men in case of chronic prostatitis, evidently due to spasmodic contraction of the sphincter elicited from the prostate. Frequent desires to urinate are sometimes the only symptom of incipient tuberculosis of the kidney. Hirt recommends the tuberculin test in these puzzling cases before the urine and bladder show essential changes. Enuresis at night has sometimes been observed in women as an additional symptom. Disturbances in the female genitalia, as also in the rectum, are liable to cause bladder disturbances. Lead poisoning and carbonic acid gas, turpentine and other intoxications frequently render urination difficult. Referring to the nervous retention of urine after operations, etc., Vogel remarks that patients with chronic cystitis or prostatitis are undoubtedly unfavorably affected by sudden chilling, especially of the skin. Appendicitis is liable to induce morbidly increased desires to urinate.

31. Roentgen Treatment of Syccosis. Scherber describes the histologic findings in a case of simple syccosis cured by Roentgen exposures. The active hyperemia of the inflammation was superseded by congestive hyperemia under the influence of the exposures. The curative action of the rays is probably due to the destruction of the cocci, supplemented by the absorption-promoting influence of the exposures.

36. Operative Treatment of Gumma of the Brain and Necrosis of the Skull. Voss reviews the cases of operative treatment of syphilitic cranial and cerebral lesions that have been published, and reports a case from his own experience. He cites 20 communications on the subject. The operation was not undertaken until after the complete failure of antisiphilitic treatment. In one instance a gummatous lesion of the frontal brain was supposed to be an affection of the motor region owing to the Jacksonian epilepsy observed. His patient was a woman of 71 in good circumstances who presented extensive necrosis of the forehead, reaching from the bridge of the nose nearly to the vertex and beyond a line through the outer margin of the orbit on both sides. The first signs of ulceration had been noted 20 years previously and the necroscopiginous lesion had

gradually attained its present proportions without impairment of the general health or causing brain symptoms until a recent secondary meningitis developed. The patient had never had any specific treatment. The necrotic part of the skull was removed and also a softened gumma beneath. As the patient roused from the anesthetic the meningitic symptoms had abated and her mind was clear. Energetic mercurial treatment was instituted at once and the patient regained health rapidly. There was no temperature and the pulse was regular until signs of intercurrent hypostatic pneumonia developed, and the patient succumbed about two weeks after the operation. In a second case, sequestra from a syphilitic lesion in the parietal bone were removed on several occasions, with the complete subsidence of all symptoms. The patient was a woman of 39. Energetic mercurial treatment had failed to relieve the symptoms of pressure on the brain.

48. Relations Between Skin and Kidney Affections.—Glaserfeld did not find evidences of a kidney affection in idiopathic atrophy of the skin, lichen or prurigo. He does not admit any causal connection between kidney affections and progressive and retrogressive nutritional disturbances, or neuritic and parasitic dermatoses, or chronic infectious processes. Occasionally the cutaneous and the kidney affection may both be due to a single primary cause. Kidney affections are frequent, however, in inflammations and circulatory disturbances in the skin. They were found almost invariably in impetigo herpetiformis, in erythematata, urticaria, purpura, eczema, acute pemphigus, circumscribed edema and Raynaud's disease. The kidney trouble is generally mild, and comes under the vague heading of "toxic nephritis." On the other hand, kidney affections are liable to be accompanied by pruritus, dermatitis exfoliativa, furunculosis, urticaria, eczema, gangrene of the skin, pemphigus and erythematata. The cutaneous affections in this case are very rebellious and generally yield only to treatment addressed to the kidneys. The article is an extensive one, based on large personal clinical experience and research.

52. Static Electricity in Treatment of Parasitic Dermatosen.—Suchier calls attention to the cure of chronic eczema, fungoid mycosis and superficial cancer which he has effected by the use of static electricity. The power need not be more than 0.5 horse power, the rotations not less than 500 nor more than 1,000, and the electrodes must terminate in a non-conducting tip of cork or wood. This enhances the effect remarkably. Seven cases are described and illustrated as typical examples of the excellent results attained. The article concludes with an array of arguments in favor of the parasitic theory of the origin of cancer. The behavior of the cancer cells under static electricity is a strong point in favor of this view, he remarks.

53. Analgesia by Endermatic Route.—Fürst applies the term endermatic to the application of drugs rubbed into the skin. He has found that gentle rubbing is not experienced unpleasantly even in case of articular rheumatism, while it is the best way to administer the salicylates, he thinks. He uses Bengue's formula: 10 equal parts of methyl salicylate and menthol with 12 parts of lanolin. He rubs a piece about the size of a bean into the joint, using a wad of cotton, and then covers the part with an impermeable dressing to prevent evaporation, repeating the application every three or four hours. The spot is washed off with tepid water twice a day. The above combination is the most powerful analgesic he has ever tried, while it does not irritate the skin. He has found it equally valuable in neuralgias, in pleuritic pains, in ovarialgia and in 2 cases of painful gastric ulcer.

54. Radiotherapy of Chronic Gonorrhoea.—Strehel's efforts to apply radiotherapy to urethral affections have been duly chronicled in these columns. He found that it was impossible to influence the urethra from without; the light must be introduced into the urethra to obtain any effect. He accomplishes this by a system of quartz rods on which a powerful electric light is concentrated. The quartz transmits the light as ultra-violet rays alone. This system is too elaborate for general use, and he has now simplified the technic, using a contrivance by which a spark passing through a quartz tube

emits a bright light, which he calls the "glimmer light." A spark from 15 to 20 cm. long is sufficient for the purpose. The quartz tube is inserted and the current turned on for from forty minutes to two hours, the aim being to induce an inflammatory reaction to the light inside the urethra. He relates his experience in detail with 3 out of 55 cases in which he has effected a cure by this means. All were of the chronic, rebellious type, refractory to all other methods of treatment. The influence of the light treatment was so unmistakable that he believes that it deserves wide attention. He has not had a failure in any instance. His "glimmer light" contains more active rays than any incandescent light he has tested.

56. Gangrene After Eclampsia.—Gutbrod has had 2 patients with eclampsia exhibit gangrene of the skin. One patient required amputation of the leg. The kidneys were so seriously affected that they were unable to eliminate all the eclampsia poisons, and he thinks that their elimination through the skin entailed the gangrene. The kidneys could not eliminate even albumin. He has always noticed that very slight albuminuria is the invariable precursor of eclampsia.

58. Treatment of Rebellious Forms of Endometritis.—Schaeffer discusses principally the treatment of the obstinate mixed infections of the uterus in middle age and also hemorrhagic cirrhotic metritis at the menopause, exfoliation of the mucosa during menstruation, and other rebellious and comparatively inaccessible affections of the uterus. He points out that glandular hyperplasia with hypoplasia of the uterus, occurring in girls or young women, is frequently a manifestation of tuberculosis, and general measures to combat tuberculosis are especially indicated in these cases. He outlines the special indications for each form of metritis, including also what he calls hypoplasia glandularis endometrii and hypoplasia or dysplasia decidue basalis.

59. Remote Results of Ventrifixation.—Weindler has been investigating the present condition of 51 women on whom ventrifixation was done by Leopold between 1896 and 1903. Of this number 38 were personally examined at least three years after the operation, and all but 8 were found absolutely free from disturbances. Eleven of the women had borne children since and the pregnancy and delivery were normal in 8 cases; the children were born before term in 2 cases. Leopold now has a record of 124 cases of ventrifixation with the best possible after-results. His technic seems to answer all purposes and Weindler says that it is applicable to all cases of retroflexion. When this technic is closely followed, he claims no disturbances are observed in subsequent pregnancies.

60. Influence of Menstruation on the General Organism.—Tobler of Florence has been investigating the local and general disturbances and the influence of menstruation on the physical and mental capacity, extending his research to 1,020 women. His summary states that the menstrual period in the women of our day is generally a time of more or less physical depression and languor. This is not as Nature intended nor is it necessary. It is the result of modern modes of life, and of a less vigorous constitution. The products of metabolism are increased in amount at this time by the periodical excitation from the genital system, but instead of being systematically

utilized to the profit of the body, they accumulate and have a toxic action. Many women do not experience this menstrual physical depression at first, but it gradually comes on them later, showing its acquired character. Other women never experience any physical depression or languor at this time. Still others find it a period of exalted vital energy and exhilaration. This latter is the theoretical ideal, and, he thinks, is probably what Nature intended for the period in which a new living being can be formed and developed.

61. Vitality of Prematurely Born Children.—Ostrell's assertions are based on the literature and on examination of 1,542 prematurely born children at the Prague maternity. He accepts 44 cm. as the minimum height and 2,000 gm. as the minimum weight for the children under discussion, and states that he was unable to find that they showed less resisting powers during their later life than children born at term. The morbidity and mortality during infancy and early childhood were not materially higher than those of ordinary children.

62. Chemical Rays in Gynecology.—Curatulo describes and illustrates an apparatus he has devised for the purpose of applying the chemical rays to the interior of the uterus. They have a sedative and resolving action as well as a bactericidal, and he thinks that they are indicated in cancerous and tuberculous processes in the female genitalia. He urges further trials of what he calls hystero-photo-therapy, prophesying a brilliant future for it.

63. Lithopedion.—The lithopedion in the case reported by Lumpe was extracted from the abdomen of a woman of 64 twenty-five years after the rupture into the abdomen of a seven-months' tubal pregnancy.

65. Causes and Treatment of Arteriosclerosis.—Klemperer describes 2 cases of arteriosclerosis in men of 37 and 44 who had long smoked from 30 to 100 cigarettes a day or from 6 to 12 cigars. The circumstances of the cases suggest that the tobacco alone was responsible for the arteriosclerosis. In another man of 45 sexual excesses were likewise the sole etiologic factor that could be discovered. The patient was unmarried and of a robust constitution. A third patient was a man of 35, married for 11 years, with two healthy children 9 and 10 years old. Since the birth of the last child intercourse had been frequent, but exclusively by coitus interruptus. These 2 cases, Klemperer states, emphasize the importance of the sexual factor in the etiology of arteriosclerosis. He reports in conclusion a case of pronounced arteriosclerosis with enlargement of the heart in a man of 52 somewhat addicted to alcohol and tobacco. The patient took 1 gm. of sodium iodid regularly for two years with remarkable subsidence of all his symptoms, the dosage one tablespoonful of a 5 per cent. solution in a glass of milk after dinner. The heart has returned to normal size and the blood pressure and tension of the vessel walls are much reduced. The systolic murmur has vanished, possibly from regeneration of something abnormal in the wall of the aorta. The patient has eaten ordinary mixed diet without regard to its lime content, but he was advised against carbonated baths.

67. Febrile Tertiary Syphilitic Affections of Viscera.—Sobernheim's first patient was a woman of 36 with enlarged liver and spleen. Once or twice a week the temperature rose abruptly, accompanied by a violent chill, vomiting and colic pains in the stomach. The temperature subsided each time with a sweat. Quinin was given without effect and also arsenic. As the liver region grew more and more painful and the febrile attacks

more frequent, the abdomen was opened and the liver exposed. It presented the typical characteristics of the syphilitic liver, and was twisted on its axis, with adhesions connecting it with the stomach. The patient was put on potassium iodid and all symptoms subsided. During the six months since she has had no disturbances, and although the liver and spleen are still enlarged they are not sensitive to pressure. The second patient was a syphilitic man of 44 whose right shoulder had been fractured in 1903. Since then there had been pulmonary disturbances, a cough and inability to lie on the left side without distress. The temperature rose high in the evening, with a slight chill; induration was noted in the lower lobe and apex of the left lung. In six weeks the entire lung had become transformed into pure cirrhotic tissue and the patient succumbed to hemoptysis. A remarkable feature of this case was the absolute inefficacy of all treatment, specific or otherwise, to influence the temperature and course of the affection. The postmortem findings are described; the changes found in the glands were sufficient to account for the hectic fever.

69. **Fluid Gelatin in Diarrhea.**—Mann and Herzberg corroborate Cohn's statement that fluid gelatin has an excellent effect in certain cases of diarrhea. If a 10 per cent. solution in distilled water is boiled for six hours and then filtered, the resulting fluid keeps clear and fluid for days. Herzberg has for years ordered a soup made of calves' feet (about one pound to one quart of water, boiled down to one pint), in diarrhea conditions in children and in typhoid fever. It checks the diarrhea while nourishing the patient. In one case severe intestinal hemorrhage was apparently arrested by it. Mann urges further trials of the fluid gelatin in non-tuberculous intestinal ulceration. In his experience the persistence of the diarrhea under the gelatin treatment indicated a tuberculous process. Such do not seem to be influenced by it.

70. **Heat in Treatment of Gonorrhea.**—Ceekas has had unusually excellent results in his local treatment of gonorrhea since he has been heating the fluids injected to about 117 F.

71. **Thermocauterization for Pruritus Ani.**—Klein applied the flat Paquelin burner to the anus and around it in a severe case of pruritus ani in a child. The cure was complete. This treatment, he suggests, might prove useful in certain cases of persistent pruritus vulvae.

72. **Cancer of the Head of the Pancreas.** In the case described there were no symptoms suggesting disturbance in the pancreas. A secondary carcinoma in the liver masked the primary growth in the pancreas, and the absence of glycosuria or any symptoms pointing to the pancreas caused this organ to be disregarded. Chronic icterus with absolute and constant intestinal acholia does not belong to the clinical picture of any variety of primary cancer of the liver. When it is observed, even with entire absence of symptoms pointing to any other organ, yet it should suggest that the primary neoplasm may be found in some other organ, pressure from which might obstruct the flow of bile.

73. **Scopolamin-Morphin Anesthesia.** Palermo reports from Tizzoni's clinic 151 cases in which the operation was performed under chloroform, preceded by an injection of scopolamin hydrobromate and morphin. It was favorably impressed, especially with the relief from apprehension before the operation and the calm sleep for two hours afterward. The patient

comes to the table drowsy or actually asleep, and there is no excitement and no vomiting afterward, with rare exceptions. (See reply to correspondent on this subject on page 1817 of the last volume of THE JOURNAL.)

74. **Acquired Dextrocardia.**—Landolfi describes 3 cases in which the heart was found at the autopsy to have undergone a double rotation on its vertical axis, bringing the apex to the right of the sternum, and on its longitudinal axis, bringing the left ventricle forward. There was also torsion of the pedicle of the heart, with a slight fold in it, not large enough to close the lumen of the aorta. The cause of the displacement was pyothorax or pneumothorax, or both. The cases indicate the importance of prompt thoracostomy when there is reason to suspect displacement of the heart.

76. **Acute Angioneurotic Edema.**—The patient was a somewhat dyspeptic man of 43 who had long suffered from attacks of supposed asthma. Four years ago edema of the face was observed, rapidly increasing to large proportions in an hour and a half and then disappearing nearly as promptly. These attacks of edema were sometimes preceded by pruritus; gradually a larger extent of surface became involved and the attacks lasted longer, sometimes for two days. The edema generally appeared during an interval between attacks of asthma. They were never observed together. Each generally followed some excess in diet, and came on abruptly, subsiding in the same way at first, but gradually the attacks became longer and the intervals shorter. Zilocchi is convinced that both are manifestations of angioneurotic edema, and that they are generated by intoxication and infection following disordered metabolism.

77. **Exclusion of the Intestine.**—Clinical experience and experimental research have convinced Longo that it is practicable and advantageous under certain circumstances to shut off part of the intestine from the digestive tract. The technic which, offers the best results is, he believes, the exclusion of the affected portion of the bowel by implanting its lower end in the lower part of the intestinal tract. This obviates the inconvenience of an artificial anus, while it also avoids the dangers of total exclusion of part of the intestine. In the case described the colon and cecum were excluded from the intestinal tract. Secretions accumulated in the excluded gut and putrefied, with resulting perforation and fatal peritonitis. In experiments on dogs this result was also observed, but nothing of the kind occurred when the excluded portion was implanted in the gut below, affording an outlet for its secretions, which were voided with the stools. Dogs thus operated on are lively and in good health months afterward.

78. **Radium Treatment of Rabies.**—See account of Tizzoni's research, page 2033 of the last volume of THE JOURNAL.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Addresses

THE THEORY OF NARCOSIS.*

PROF. HANS MEYER,
University of Vienna.

I esteem it a high honor as well as a great pleasure to address you on this occasion and to have been asked to open the first course of lectures of the Harvey Society. The establishment of these lectures is additional evidence, if such be required, of the great interest displayed by American physicians in theoretical conceptions and in scientific research, and, in addition, of an earnest effort to encourage and diffuse such knowledge.

I look, however, on the invitation extended to me as evidence of your friendly and fraternal sentiments toward the whole body of German scientists, and I may be permitted on their behalf to offer you an expression of their cordial appreciation.

Following the suggestion of your president, I have selected as a theme for this evening's lecture a subject which, for a long time, has repeatedly attracted and interested not only pharmacologists, but biologists as well, namely, the relationship between the pharmacologic action of a drug and its recognized chemical or physical properties. The solution of this problem presents great difficulties. Even with a knowledge of the chemical and physical properties of an active substance it is yet impossible, without further knowledge, to determine which of these properties is responsible for the specific action on the animal organism. And this the more so, since we do not know the chemical point of attack in the organism, and hence can not know the nature of the chemical reactions which occur between poison and protoplasm. Only in one way can we reach a conclusion that admits of probability. If we find a large series of different substances with different chemical and physical properties, which all possess identical or else very similar pharmacologic actions, then we can fix on the chemical and physical properties common to all and on which the common pharmacologic action naturally depends. So, for example, out of a mass of keys different yet all able to open the same lock we can determine which part of each key is the essential one, what form common to all fits the lock. And it is hardly necessary to point out that from this we can obtain an insight into the construction of the lock itself. In our case this means an insight into the chemical organization of protoplasm.

The first experiment in this direction was made by two English investigators—Crum-Brown and Fraser. They discovered the notable fact that practically all the ammonium bases, that is, organic bases in which the pentavalent nitrogen is connected with four valencies to carbon, exercise the same pharmacologic action, regardless of other differences in their constitution and nature;

the action in this case being the same as that of curare, a paralysis of motor nerves. This definite relationship has been confirmed by many investigators, but the explanation for it is still lacking. It appears to me possible that the strongly basic character of all these ammonium bases is the chief factor. They are much more strongly basic than alkaloïds and even sodium and potassium, and the few exceptions, such as betain, antipyrin and others which do not possess this strongly basic character, are also without the curare-like action.

Another series of experiments along this same direction, in connection with the action of the neutral alkali salts, has been conducted by Hofmeister. He has shown that all the effects of these salts, including their laxative and diuretic actions, may be explained by their physical properties, their diffusibility and osmotic strength.

This brings us to a third especially large group of substances whose actions are all identical in principle. I refer to those substances which are commonly designated anesthetics. To this group belong bodies quite distinct from each other chemically; alcohols, aldehyds, ketones, esters, ethers and numberless others. They all possess the common action of depressing the central nervous system. Wherein is the relationship? On which of their common properties is their narcotizing action dependent? The chemical composition of the nervous system itself gives the first clue for an understanding. It differs from all other tissues in its richness in fat-like constituents, and on the basis of this peculiarity Bibra and Harles attempted many years ago to explain the action of anesthetics. They found that the anesthetics dissolved ordinary fat, and, as a result of a quantitative estimation of the fat content of the brain of a normal and narcotized animal, assumed that the anesthetics directly removed fat-like substances from the brain. But these conclusions could not be confirmed. From another standpoint, however, Hermann arrived at a similar opinion of the action of narcotics. Hermann had discovered the presence of lecithin in the red blood cells, and since the anesthetics, such as ether, chloroform, etc., dissolve the blood cells, he explained this by their power of dissolving lecithin, and pointed out the parallelism between this process and the narcosis of the central nervous system. In both of these hypotheses there appeared to me to be an element of truth, and in order to establish this and define its character I myself instituted a series of experiments.

I started with the following assumption: If fat-solubility is indeed a necessary condition for narcotic action it is to be expected that all indifferent, fat-soluble substances must act as narcotics if they can enter the cells, and that, on the other hand, if by any circumstance they lose their fat-soluble property, then they must also become inactive. I have tested this assumption by investigating a series of substances made by combining components which in themselves had no narcotic action, but whose combinations were soluble in

* This, the first lecture in the Harvey Society course, was delivered at the New York Academy of Medicine, Oct. 7, 1905.

fat. As examples may be mentioned the amides of organic acids. These amides are neutral compounds which are soluble in fat and which all possess the typical narcotic action, with, however, one single exception, carbamide, and this particular one is insoluble in fat. Another group (comparable to the amides) is composed of condensation products of glycerin; the chlorhydrins, acetins and glycerin-ether. These also are soluble in fat and act as narcotics. All these substances, however, are very readily split up by hydrolysis into components insoluble in fat and on such decomposition lose immediately their narcotic power.¹

Now, if from these and similar observations the conclusion can be drawn that the solubility of an anesthetic in fat is certainly one of the conditions for narcosis, the further question presents itself whether this condition is an essential one and whether it can be utilized as a measure of narcotic power. Were this the case, a quantitative relationship between narcotic power and solubility in fat must exist. But it is obvious that other factors must influence the action of narcotics in the animal body, for their affinity for the watery components of the body, as well as that for the fat-like constituents, must be considered. According to their relative solubility in the fat-like and non-fat-like constituents of the body they will distribute themselves between those constituents. So, for example, such substances as are very little soluble in water will dissolve for the most part in the fat-like constituents.

Richet had previously made the observation that the anesthetics which are little soluble in water possess a marked narcotic action, and he regarded this relationship as a general law. As a matter of fact, however, from this single relationship no general law can be deduced, for substances such as alcohol and chloral, which are both equally soluble in water, possess very different narcotic powers. The proper expression of the law must, therefore, be that the distribution relationship, the so-called distribution coefficient, of the narcotics between fatty and watery solutions, is the determining factor of narcotic action. To test the correctness of this hypothetical law I have determined the strength of action of a large number of different narcotic poisons by estimating the smallest molecular concentration of their solutions which was sufficient to induce narcosis of small fish and tadpoles placed in them. A second series of experiments was then carried out with the same substances for the purpose of determining their distribution coefficient between water and fat. A mixture of water and oil was used to estimate the relative quantities passing into these two substances. The comparison between the distribution coefficient so obtained and the narcotic strength of the narcotics did, as a matter of fact, yield the expected result, as a glance at the following table reveals:

TABLE SHOWING THE RELATIONS BETWEEN THE DISTRIBUTION COEFFICIENTS, P. W., AND THE CONCENTRATIONS, EXPRESSED IN GRAM MOLECULES OF SOLUTIONS INDUCING EQUAL NARCOTIC ACTION.

	P. W.	Concentration.
Tropaeol	4.4	0.0013
Urethane	1.6	0.0018
Butylchloral	1.6	0.002
Sulphonal	3.1	0.0067
Bromalhydrate	0.7	0.002
Bromazonal	0.6	0.002
Picrostin	0.2	0.016
Fluacetin	0.23	0.015
Chloralhydrate	0.22	0.025
Acetylurethane	0.11	0.025
Monoacetin	0.063	0.027
Methylurethane	0.04	0.1
Ethyl alcohol	0.03	0.5

1. The amides yield fatty acid, and ammonium salts, the glycerin derivatives, glycerin and acetic or hydrochloric acids.

With an increase in the distribution coefficient there occurs an almost parallel increase in the narcotic strength, that is, decrease in the molecular concentration necessary for narcosis. The few departures from the general rule which occur in the table can be explained by the naturally inexact method of estimating the narcotic power.

A further proof of the correctness of the view described may be offered. It is known that the solubility of most substances in water and fat changes in a different way with variations in temperature. The distribution coefficient is also variable according to temperature. It must be expected, then, that the narcotic strength as well will vary with changes in temperature. And this is the fact. I examined six substances, of which with higher temperature three gave higher and three lower distribution coefficients. And it was found that in exact accordance with the rise or fall of the distribution coefficient so the narcotic strength rose or fell, so that tadpoles which were just narcotized by a certain chloralhydrate solution at 30 degrees C. were aroused and quite active on cooling to 3 degrees, and on subsequently warming to from 25 to 30 degrees again passed into narcosis. From this the direct dependence of narcosis on the physical relationship of the narcotic to the fat-like substances, the lipoids of the body, and the watery constituents seems to be definitely proved.

As a result of all these studies we arrive at the following explanation of narcosis: The narcotizing substance enters into a loose physico-chemical combination with the vitally important lipoids of the cell, perhaps with the lecithin, and in so doing changes their normal relationship to the other cell constituents, through which an inhibition of the entire cell chemism results. It also becomes evident that the narcosis immediately disappears as soon as the loose, reversible combination, dependent on the solution tension, breaks up. It follows further that substances chemically absolutely indifferent, as the volatile saturated hydrocarbons, can act as narcotics.

Quite in opposition to this idea, it has been frequently put forward and accepted that the breaking up of the narcotics, with a chemical action of definite atomic groups thus set free, as the ethyl group, for instance, is responsible for the narcosis. But even in the case of sulphonal and its related sulphones, from which this idea originates, it can be shown that the action is induced by the entire unchanged molecule, and that the lack of activity of certain sulphones is due not, as is generally believed, to their not being broken up, but to a low distribution coefficient.

This simple theory also explains the fact that all structures capable of stimulation, not only the cells of the nervous system, but all others, and all plant cells as well, are depressed by the narcotic members of this series, for in all living cells lecithin, a lipid body, is to be found. And, indeed, the establishment of the fact that the effect on the lipoids by narcotics, such as ether and chloroform, is such as to immediately inhibit the vital processes of the cell, shows us that these lipoids are among the constituents essential to the life of the cell. Moreover, by establishing this fact it seems to me that the general biologic significance of the theory becomes apparent.

That many narcotics induce not pure narcosis alone, but often show other distinct actions, as, for example, the occurrence of convulsions, which quite overshadow any narcosis present, is easily to be understood when

one remembers that the narcotics may possess an affinity not only for the cell lipoids but for other cell constituents as well, and through some union with these, concomitant effects quite different from narcosis may be induced. This occurs, for instance, in the case of the phenols, whose narcotic action is thrown into the background by the appearance of clonic spinal convulsions.

No attempt is made to explain every type of narcosis by means of the theory presented here. It is very probable that some other disturbances in chemical equilibrium can occur in the cell and inhibit the performance of its function and that substances such as morphin are narcotic through their relationship to other points of attack than the "alcohol lipoids": and most probably the same can be said concerning the very remarkable narcosis from magnesium salts, lately discovered by Meltzer.

I desire to add in conclusion that shortly after I had published my theory of alcohol narcosis the physiologist Overton published experiments which, carried out independently of mine and from a different point of view, in fact, with somewhat different methods, brought him to an identical conclusion, i. e., to a similar theory of narcosis, so that he has confirmed my work and accepted the formulation of my theory literally. I take this as a strong and gratifying argument for the correctness of our assumption.

THE BREADTH OF THE PROFESSION OF MEDICINE.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON NERVOUS AND MENTAL DISEASES, AT THE FIFTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, PORTLAND, ORE., JULY 11-14, 1905.

JAMES H. M'BRIDE, M.D.
PASADENA, CAL.

While the past year has been one of general progress in the specialty, there do not appear to have been any notable discoveries. I shall therefore refer in this official address to other matters that may be of interest.

In the development of medicine, as elsewhere in the growth of knowledge, investigations that have important results are rare and great discoveries are rarer still. We can not expect that progress shall be a steady onward movement, for of necessity it is irregular. The spiral stair, to use Emerson's phrase, is the law of all growth. All knowledge has had far origins and has come to us by devious paths; there have been pauses, lapses, rests and infinite failures before the goal was reached. I refer to this because in our day we are expectant and a little anxious, if not impatient, that rapid advance be made in medical knowledge, and because of this medical men have sometimes in the past hastily accepted discoveries without waiting for the test of time and use.

It is fortunate that the profession is now more intelligently critical than formerly of the work of investigators. The physician is an optimist, and the past justifies him in his attitude. Professionally, he is the lineal descendant of men who, in more primitive times, claimed to cure disease by charms and incantations and the laying on of hands. Though he knows, for instance, that the professional forbears of the astronomers were the simple Chaldean shepherds of four thousand years ago, and that all science had a like rude beginning, yet he holds that progress in medicine has been quite as great as that of any science.

There is some danger, however, that he will accept as

demonstrated fact, the guesses of investigators in whom imagination may be more active than judgment. Fortunately, however, the investigator of to-day appeals to a more critical audience. Every claim to a discovery is now passed on by what is practically a technical board, where the always necessary test of criticism is applied and that which is valuable is saved.

Every physician should be an original investigator; it is one of the obligations of his calling. Medical practice daily offers opportunities for original research. The great experimenters have done much for the advancement of medicine, but the great practitioners and surgeons have done more. There is no better laboratory than the bedside. The most elaborate equipment for scientific medical investigation is a small affair in comparison to the opportunities of the sick room. The laboratory may suggest, confirm or explain, but it must always be secondary to bedside study. If we are ever able to cut our way through the jungle of problems that human disease presents, we will accomplish it chiefly by the study of the sick, or to use John Locke's splendid phrase, "by the study of the natural history of disease." It is through this bedside study that progress in neurology has chiefly been made, helpful though experimental work has been. As experimental physiology has gone about as far, in this regard, as it can at present, progress in the immediate future will probably be chiefly due to clinical investigation.

It is primarily the business of the physician to prevent and cure disease. The greatest triumphs of the future will doubtless be in the line of prevention, but it is probable also that therapeutics will always be in vogue. If one might judge from the small number of papers contributed to this Section from year to year on the subject of therapeutics, our members are not specially interested in the subject. Four years ago the chairman called attention to this and urged a greater interest in therapeutics, but it does not appear that there has been any increase of interest in the subject by the members of this Section since that criticism was made.

It is hardly possible that we have reached the limit in the application of remedies in the treatment of disease of the nervous system. If the members of this Section could carry on a collective investigation, extending over two or three years on any one of several subjects, the results might be valuable. Notwithstanding the volumes that have been written on the applications of hydrotherapy to nervous diseases, there are yet many obscure points to be investigated, and collective investigation along this line alone could be made profitable.

It is pre-eminently true of nervous and mental diseases that therapeutics is not a thing of drugs only. Aside from seclusion, rest, exercise and hydrotherapy, which are now part of the therapeutics of nervous diseases, the future will undoubtedly disclose remedial measures, other than drugs, that will be of value. We now emphasize the importance of all those things that make up, not alone the physical but the psychical environment of the individual; more and more we see that the cure of the nervously disordered is not so much by drugs as by the influences which we may bring to act on the psychic side of the patient's life. Rest and seclusion in neurasthenia and proper environment, muscle drill and rest in tabes, kindness and diversion in insanity are great advances over the treatment of a generation ago, though we are probably at the beginning of this larger view of therapeutics in these and other disorders.

Quacks and charlatans have made such prominent and noisy pretense of skill in the way of utilizing the mental life as an aid in treatment that reputable physicians have hesitated to claim any interest or confidence in it. It is, too, a phase of treatment that is particularly liable to misrepresentation, abuse and over-statement.

It is possible, I admit, however, with hesitation, that there is a place in medical practice for systematic mental therapeutics, and if proper attention were paid to it, it might result in it being taken out of the hands of mental healers and their like, as the profession took surgery out of the hands of barbers and pretenders.

All such departures from accepted methods, the breaking away from the conservatism and practices of the past, are not easy, but it is desirable that we consider it without prejudice.

It is not long since the use of both electricity and hydrotherapy were practically under the ban of the profession, and yet to-day they are among the most valuable remedies that we have.

From a fairly intimate professional acquaintance with myself, I should say that members of our specialty are liable to become narrow in their views of general medical practice, and yet there is no specialty where it is more important that the physician be well informed in general medicine and quick to recognize the possible relations of nervous and mental diseases to any and all morbid conditions. The alienist and neurologist should be first a good general practitioner, and if he is not he will fall short of what the specialty demands.

All this requires that the physician should not only be a progressive man, but an opportunist, ready to take advantage of any and all methods and means that will help to cure disease. Medicine is first an art, and only by courtesy of charitable qualification can it be called a science. This animal body is too intricate a structure and complex and variable in function to permit as yet of its morbid perversions being brought within the exact order that a science demands.

It is all the more important, therefore, that the physician be an open-minded and progressive man, for he is simply a seeker after the best means to accomplish an immediate end, and is free to use any means that he can command that bring results.

There is no profession whose members are less trammelled by precedent, tradition or prejudice than ours. Our code of ethics is the code of a square deal. Our only creed is that of the gentleman. Every physician is free to choose his methods and remedies. No decisions and no precedents limit the applications of his logic, no councils instruct him where he shall go for facts. He can go contrary to all usages and introduce revolutionary methods, and the profession welcomes his work, if only it is justified by results.

It is not to the discredit, it is to the glory of medicine, that it changes. The world of knowledge grows; sciences are forced being reconstituted, and medicine must meet the demands of change and growth. We systematize our observations and call them science, but methods change, observations are made by newer and better methods, new facts come to replace and modify those we have, old remedies are abandoned, old theories are recast, and by this incessant change and rearrangement we attain to accuracy and definiteness.

Nearly two thousand years ago a Roman physician said that there seemed to be nothing left for the future physician to discover. The man who has always lived on a little island and has had no news of other lands

may be excused for thinking that the ocean washes no shores but his. This Roman doctor in relation to science lived on an island, and even this has shrunk to a microscopic speck on the map of later knowledge. What he called medical science and considered final, has for us only an archeologic interest; of that primitive structure of knowledge which he helped to rear, we have hardly left one stone on another. We realize as true what he did not suspect, that human knowledge is always in the making; that there is no finality possible for us, for from the very necessity of existence we are subject to incessant change. We must, decade after decade, look out from other heights, rearrange our facts, reconstruct our knowledge and reconstitute our best philosophy.

In spite of all the discoveries of medicine, in spite of all the facts that physicians have put in tomes, we are yet at the beginning of what medicine will be; we are explorers who have but touched the capes and promontories of an unknown continent.

Every doctor who stands for progress and values principle above the transient results of mere success is a contributor to the growth of medicine in the best sense. Anyone who demonstrates a new fact has raised the level of knowledge and added to the momentum of our advance. The articles that we contribute and the discussions we have here, may be of transient value, but if the work is done in the right spirit it stimulates to effort and helps to maintain that enthusiasm that is in a large measure the motive power of all progress.

Everyone should come here with his best thought, and if he is wise, he will go away with his ideas changed and clarified and with new interest and increased power for good.

We must rank among our greatest helpers, not alone those who teach us most, but those also who inspire us most, for if it is the inspirers of men who have been the chief instruments of progress.

May we all receive such inspiration when we come here as will help us to be true to the highest ideals of our profession, and in company with all who hope and strive and care, even we in our humble lives may illustrate the best traditions of our profession.

Suprarenal Treatment of Cancer.—Berdier and Falabert presented a communication to the last Latin-American Medical Congress relating the excellent results attained in a number of cases of cancer by local injections of extract of the suprarenals. Under the injections and local applications of the extract the tumor and the glands in the vicinity became reduced in size, while the pains subsided and the patients gained in weight and strength and felt generally much better. Patients who had been unable to get relief from pain except with morphia found that the pains vanished under this local treatment. They say that some connection between the suprarenals and the evolution of cancer seems a plausible assumption from the facts observed. In a case of cancer of the rhino-pharynx, in a man of 52, .5 mg. of adrenalin was injected into the most accessible part of the growth, this injection repeated daily. By the fifth day the patient's deafness had much improved and the growth had commenced to subside. After a dozen injections, in the course of a month or so, the patient was restored to apparent health, with scarcely a trace left of the tumor in his throat, and he has been in good health since. In other cases the relief of the pain by the injections was notable, even when the cancer was too far advanced for treatment to be more than palliative. When the cancer was in the stomach or other internal organ, the suprarenal extract was injected into the arm. The article is given in full in the *Escuela de Medicina*, of Mexico, for Dec. 31, 1905. Histologic examination of the growth was not made in every case.

THE RHYTHMIC SOUNDS OF THE ALIMENTARY CANAL.*

W. B. CANNON, M.D.

Assistant Professor of Physiology, Harvard Medical School.
BOSTON.

The sounds produced by the alimentary canal were noted by the Father of Medicine, who is said to have first used the term "borborygmi" to describe the loud rumblings arising in the abdomen. In later times little discriminating attention has been paid to abdominal sounds. Hooker¹ published an essay in 1849 in which he describes more or less alteration in the intensity of the sounds made by the alimentary canal in different diseases of the digestive organs. Other writers have classified the sounds normally audible into splashing, rattling or rustling noises, the murmurs of respiration and of the aorta.²

These sounds, however, according to L. Bernard,³ are not constant over the abdominal organs, nor do the sounds characteristic of the healthy individual alter in pathologic conditions. Little else than these statements is found in the most recent treatises on auscultation. Rubbing noises are mentioned in cases of inflammation, and piping notes when there is stenosis of the intestine. More than this is not stated.⁴ Any special attention to the qualities of certain sounds in the general confusion of noises in the abdomen was hardly to be expected so long as the character of the movements of the stomach and intestines was not thoroughly known.

Within a few years the nature of the motor activities of the alimentary canal has been definitely determined,⁵ and this new knowledge should make possible an association between the motor activities and the sounds attendant on them.

The most characteristic feature of the movements of the alimentary canal is undoubtedly their *rhythmicity*. Over the stomach peristaltic waves pass in rhythmic succession; in the small intestine the most usual activity is a rhythmic segmentation of the food; and in the ascending colon antiperistaltic waves, during short periods, rhythmically follow one another toward the cecum. The most favorable condition for the production of sounds in the alimentary canal is the presence of gas of some sort mixed with the more or less fluid food. When the food and the gas are churned together a sound must result. It is possible to introduce air in fine division with the food by eating, along with other food, a cheese soufflé, toast slightly chewed, very porous bread, or a fluffy omelette. When such food is taken, and frequently after ordinary meals, rhythmic sounds can be heard over the pyloric end of the stomach and later over the lower part of the abdomen.

In listening to these sounds I have made use of a Bowles stethoscope with a rubber tube long enough to permit the hard rubber disc to lie at any point on the abdomen. It has been my custom during the past few months to keep the stethoscope at the head of my bed, and when unable to sleep I have amused myself by lis-

tening to the sounds produced by the digestive organs. At times in the quiet of the night it is possible to hear the sounds without the stethoscope. Sometimes the vibrations produced are so strong that they can be perceived, like the tactile fremitus of the chest, by placing the hand over the region in which the sound arises. The rhythmic sounds are not due to respiration; they differ in rate and in time from the respiratory movements. They are not due, as a listener might at first suppose, to the arbitrary choice of a rate and the selection of such sounds out of the confusion as occur at the proper time to make the rate good. I have been able to eliminate entirely the personal element from the registering of these sounds. By means of a telephone transmitter placed over the abdomen and activating, through an induction coil, a nerve-muscle preparation, I have secured graphic records of the sounds made by the stomach and small intestine wholly without the mediation of human judgment. This method was used by Hürthle⁶ in recording the heart sounds.

THE SOUNDS OF THE STOMACH.

The active end of the stomach is the pyloric end. The food is pushed by peristaltic waves moving toward the pylorus. If the pylorus does not relax as the ring of constriction approaches, the only escape for the food is away from the pylorus through the advancing ring. As the waves are recurring continuously and the pylorus relaxes only occasionally, the food near the pylorus must be squeezed and regurgitated by almost every constriction ring. And the food escaping through the narrow orifice must, if mixed with gas, produce a sound. Since the pyloric end of the stomach reaches farther to the right and to the front than any other part, it is clear that lying on the left side of the body, or on the back and left side, will bring the pyloric end uppermost. When the stomach is so situated, the lighter food, i. e., food mixed with gas, will naturally rise into the pyloric end, and peristaltic waves, for reasons already stated, will then cause sounds to appear. Sounds heard recurring regularly when the person listened to was on the left side, entirely disappeared or became very faint when the person turned so that the pyloric end became lowermost.

The stomach sounds can best be heard after a somewhat bountiful meal, as, for example, an hour after dinner in the evening. The disc of the stethoscope should be placed near the end of the eighth rib on the right side. The sounds heard are usually loud, rattling, explosive and of characteristic quality. At times the sounds may last several seconds. In some persons they are louder and more regular in their occurrence than in others. The rate of recurrence of the gastric sounds varies in the neighborhood of one sound every 20 seconds. In one person the rate was strikingly regular, one sound every 17 seconds, in another every 22 seconds, and in another every 23 to 24 seconds. That these sounds are a true indication of gastric peristalsis is confirmed by the observations of Moritz,⁷ who recorded a rhythmic increase of intragastric pressure in the pyloric end of his stomach at twenty-second intervals.

Fig. 1 is the copy of a record, secured by the telephone method previously mentioned, which shows graphically many of the features of the stomach sounds. The different heights of the separate marks indicate variations in the intensity of the sounds. The duration of the sounds also can be judged; for example, at *c* and *e* they are more prolonged than before *a*. One of the pop sounds, heard in all parts of the abdomen, is recorded

at *a*. Silent intervals, which occur occasionally, are indicated in the regions *b*, *d* and *f*. In these regions arrows have been placed at the points where the sounds would have recorded if present. The regular rhythm is resumed in continuation of the previous rhythm. It should not be supposed that the silent intervals are always as frequent as this record shows them; I have one tracing in which the marks are not only rhythmically regular, but of almost the same height, uninterruptedly for fifteen minutes.

THE SOUNDS OF THE SMALL INTESTINE.

The possibility of making use of the sounds attending movements of the alimentary canal was suggested by hearing rhythmic sounds as, in an anesthetized cat with opened abdomen, I watched the rhythmic segmenting movements of the small intestine.⁸ With each contraction on the circular fibers the enclosed food was squeezed into the region of the former intermediate constrictions, and the sound then recurred. I have observed these rhythmic movements of the small intestine not only in the cat, but in the dog and rat. They occur at a more rapid rate than the stomach movements. In the cat the stomach movements are seen 4 to 6 per minute, the segmenting movements sometimes 18 to 21, sometimes 28 to 30 per minute.

Fig. 1.—Graphic record of the stomach sounds secured by placing over the pyloric region a telephone transmitter activating a nerve-muscle preparation. The time is marked in seconds.

Fig. 2.—Graphic record of the rhythmic sounds of the small intestine. The height of the records has been reduced to about one fourth the original size. The time is marked in seconds.

Usually listening over the lower abdomen, especially over the right lower quadrant, during the height of digestion, reveals a great confusion of noises. It is unsafe to attempt to distinguish for the first time the rhythm of the small intestine in the midst of this chaos. It is much better to listen at first in the night, or, better still, an hour or two after awakening in the morning and before breakfast. The stomach is then producing no sounds, and by placing the disc of the stethoscope in the lower left quadrant the active part of the large intestine is avoided.

The rhythmic sounds of the small intestine are very different from the gushing, explosive sounds of the stomach. The rhythmic sounds vary in quality; sometimes a soft, muffled rustling; sometimes a group of little, rattling, explosive discharges, and sometimes a rough rolling rumble like miniature thunder. But with these variations there are three features that are quite distinctive. The first of these is the slow crescendo, followed by a diminuendo in the sound, so that each sound lasts two or three seconds or more; the second characteristic is the persistence of the rhythm for some time in one place—it does not move on as a

peristaltic wave would move; and the third feature is the distinctive rate, which is usually one sound every 7 or 8 seconds. I have heard the sounds only 4 or 5 seconds apart and at times even 10 seconds apart, but the common interval is 7 or 8 seconds. This fact and the rate of gastric peristalsis as determined by this method I reported before the American Gastroenterological Association, April 24, 1905.⁹

In the morning, after an ample dinner the previous evening I have heard these rhythmic sounds continue for more than an hour and a half without interruption. They are not peculiar to the morning hours, though they are most clearly distinguished at that time. After learning their character I have heard them clearly in the midst of active digestion in the afternoon.

A record of the rhythmic sounds of the small intestine, secured by the method already mentioned, is shown in Figure 2. It is a record of sounds heard before breakfast one morning about half-past nine o'clock. The dinner at six o'clock the previous evening consisted of grape fruit, mackerel, potato, cucumber and tomato salad, four slices of bread and butter, and strawberries and cream with coconut cakes. About ten o'clock in the evening four slices of bread and butter and a glass of milk were taken. At the time this record was made the telephone

transmitter was placed on the lower left quadrant of the abdomen. The duration of the sounds is not indicated, since the muscle recorded in each case only at the climax of intensity.

THE SOUND OF THE LARGE INTESTINE.

The antiperistalsis of the proximal portion of the large intestine was incidentally observed in the cat by Jacoby¹⁰ in 1890 during a research on colchicum poisoning. In 1902 this activity of the large intestine was established as the normal activity in the undisturbed animal by observations with the Roentgen rays.¹¹ In 1904 Elliott and Barclay-Smith¹² confirmed these observations on the cat and found that in the rat and guinea-pig, and to a slight extent in the rabbit, hedgehog and ferret, antiperistalsis was present in the proximal colon. They also found in the herbivorous animals they studied that sacculation of the proximal colon was associated with churning movements, each sacculus becoming at times the seat of swaying oscillations. The greater the churning activity of the proximal colon the more marked

churning activity of the proximal colon the more marked was the sacculation of its wall. The colon of man is of the sacculated herbivorous, rather than of the carnivorous type. The sign of a proximal colon which mixes and churns its contained food is a uniform soft consistency of the contents. In the human being this condition is realized only in the cecum and ascending colon; the contents of the transverse colon are generally as firm as those of the rectum.¹³ Elliott and Barclay-Smith assumed, therefore, that in man the food entering the proximal colon "is still delayed by a backward current, still commingled by the activity of the walls of the sacculi."

The greater activity in the right lower quadrant of the abdomen is manifested at times by an almost constant succession of little popping noises and faint gurglings when the left lower quadrant is quite silent. In spite, however, of listening in the region of the cecum for hours, at different times of the day, and with my body in various positions, a uniform and characteristic rhythm of the sounds in this region, if it be present, has escaped me. Sounds of a coarse rumbling character somewhat like those of the stomach, but usually more prolonged, are audible at times. These sounds were once heard recurring regularly for a short period at intervals of about 20 seconds. More commonly in my experience such irregular intervals as these—45, 25, 35, 27, 25, 14 and 29 seconds—are observable. Inasmuch as these sounds are not clearly rhythmic it seems questionable whether they are produced in only one part of the intestine. These gurglings are heard loudest along the ascending and transverse colon, and for that reason are probably due to activities of the large bowel.¹⁴

Enemata of starch and a little flour boiled in normal salt solution, stirred into a froth much like soapsuds, and introduced at body temperature in amounts varying between 1500 c.c. and 3000 c.c., if the body is kept horizontal, can be retained for a half hour or more without difficulty. During this time there are repeated pains or cramps referred most commonly to the region of the hepatic flexure of the colon. They are very distinct and quite unmistakable in their character. It is remarkable that these recurring cramps, which are undoubtedly due to contractions of the intestine, are ordinarily not felt in the descending colon, sigmoid flexure, or rectum, but are restricted to the proximal colon, the region which in lower animals is characterized by the greatest activity.

The contractions attending the pains are not expulsive. Nor do they seem to move backward from the part in which they are felt, for no sound is audible over the cecum either during the pain in the hepatic flexure or after it has disappeared. The contractions apparently occur again and again in the same region without moving in either direction. I have observed¹⁵ in the cat such repeated circular contractions of the proximal colon, but they are not usual.

The recurrent pains ordinarily last from 6 to 8 seconds, increasing gradually in intensity until just before the end. They are commonly attended by gurgling noises, audible as the cramp is passing away. The cramps have been observed succeeding one another for nearly 10 minutes at intervals varying between 19 and 22 seconds, but in my experience they are not ordinarily

so regular as this. The following figures, representing in seconds the time between the onset of successive cramps, illustrate the usual rather irregular recurrence of the contractions:

28	39	22	43
47	35	15	42
35	15	25	40
32	15	50	45
23	18	40	64
41	35	25	37

From evidence secured by auscultation and sensations of cramp, it seems certain that the ascending and first part of the transverse colon are more active than the remainder of the large intestine. That there is an antiperistalsis in this more active region is not yet established. As already mentioned, Elliott and Barclay-Smith have found that such sacculations as occurs in the human colon is associated with emphasized churning activity of the walls of the sacculi. In repeating their observations on the guinea-pig and rabbit I have seen oscillating movements of single sacculi, now here, now there, or of many sacculi at the same time, each contracting repeatedly, squeezing out the contents of the pouch, crowding full the neighboring pouches which in turn become active, then relaxing, filling, and discharging, again and again, till the food is thoroughly churned. Such a process could not be attended by a clearly marked rhythm—too many little activities are going on at the same time. These little activities would naturally be attended by the continuous popping noises and the slight gurglings which are heard at times over the ascending colon. Is it not likely that in man oscillating contractions of the walls of the sacculi, rather than antiperistalsis, is the prominent operation of the proximal large intestine? In accord with this suggestion is the observation above mentioned that the pains in the colon occur repeatedly in the same region, and do not spread to neighboring parts.

A characteristic sound, not periodic, which is audible at times along the transverse and descending colon is a progression of little crackling noises like the breaking of minute bubbles. The sound starts in the transverse colon and its advance can be clearly traced. If the disc of the stethoscope lies over the splenic flexure the crackling can be heard first faintly, then louder and louder, then gradually more faintly again, and if after the climax of intensity there the stethoscope is changed to a position farther along the large intestine the sound can again be heard passing through the same phases as before. This sound is likely to be followed immediately by a tendency to pass gas from the bowel.

VALUE OF THESE DATA.

To one listening for the first time for rhythmic abdominal sounds, probably the most striking feature of what he hears is the large number of sounds which are not rhythmic. Most prominent among these irregular sounds are the sudden quick discharges or pops which can be heard, either singly or in a short series of three or four, almost at all times and in all parts of the abdomen, though most frequently on the right side. As already stated, these reports resemble the sound of bursting bubbles, and it may be that they are caused by the squeezing of gas from a mass of the food by general pressure of the intestinal wall. Occasionally a continuous little gurgling can be heard for some moments, gradually becoming less intense. It seems probable that peristalsis in the small intestine is thus manifested.

Whether the observation of the sounds of the stomach and intestines is to be of clinical importance will depend on whether or not there are typical variations of these sounds in different diseases of the alimentary

13. Rolth; Merkel and Bonnet's Arbeiten, 1903, vol. xx, p. 32.

14. Dr. S. J. Meltzer, in an article on the sounds of swallowing, in Berl. Klin. Wochts., 1884, No. 30, mentions certain loud noises which he heard in the region of the liver and which he attributed to the passage of food through the pylorus. Inasmuch as loud sounds are not falling into the gastric rhythm are heard in this region it is impossible to be certain that what he heard were really *Pylorusgeräusche*.

canal. The observations here recorded, made chiefly on myself, have been confirmed on other normal individuals. No attempt has been made to study the sounds produced in abnormal conditions. It has occurred to me that the method might be used to separate the somewhat vague expression "motor insufficiency" into its two factors, absence of peristalsis and pyloric obstruction. Evidently if sounds recur in regular rhythm at the pylorus, and food remains in the stomach, the so-called "motor insufficiency" is due not to absence of peristalsis, but to difficulty at the pylorus. This is only one of the applications which the method may have. In such disorders as gastritis, nervous dyspepsia, atony, colic, peritonitis and dysentery a study of the sounds produced by the movements of the alimentary canal, both before and after the administration of drugs, may reveal facts important to the clinician.

REST IN PULMONARY TUBERCULOSIS.

J. G. HILLEARY, M.D.
DUBOIS, PA.

I wish to make a plea addressed to the general practitioner for the routine employment of rest in the open air in all active or partially arrested cases of tuberculosis. In the vast majority of cases the general practitioner is the man who is called on to diagnose and to treat these patients, and as he has been lectured, criticized and capoted into making an early diagnosis only to meet with failure in the treatment, I do not think it amiss to point out the error that is responsible for failure, in nine times out of ten in otherwise curable cases, viz., exercise. Even to-day, with the overwhelming proof of the curability of this disease, many physicians say that they do not believe it can be cured, while others say that it can be cured only in sanatoria. When the details of their treatment are gone into it will be found that the greatest mistake is in indiscriminate exercise and lack of proper supervision. This unfortunate experience has bred indifference till at the present time the physician in general practice advises a change of climate, and when this is impossible, which is so often the case, quietly folds his hands, gives an unfavorable prognosis and leaves the unhappy victim to his fate. Let it be distinctly understood that I am not advocating rest to the exclusion of any other means that we possess to combat this disease. Food, personal hygiene, hydrotherapy and strict supervision should be used in the effort to effect a cure.

HISTORY OF THE REST CURE.

Deitweiler of Falkenstein, a student of Brehmer, originated the rest cure in the open air. Having seen the failures in the practice of Brehmer, who ordered all patients not bed-ridden to indulge in systematic walking, he advised the rest treatment, and is as enthusiastic regarding its virtues to-day as he ever was. This method of treatment has been denounced by Nauman and Freudenenthal, but nevertheless it is recognized as an indispensable aid in the treatment of this disease by the best clinicians the world over.

MODE OF ADMINISTRATION.

If possible all patients running a temperature of 101 F. or over should be put to bed on a piazza connecting with a room by a door or large window. With this arrangement the patient can be brought in the room, which should be comfortably warm, for his meals, and to be bathed, etc. In the afebrile cases or in those pa-

tients with a maximum temperature of 101 F. or less, the patient should sleep out of doors or in a large room with the windows open. At 7 a. m. he should be dressed with as little effort on his part as possible, have his breakfast and be out in the open air by 8 a. m., where he sits warmly wrapped in blankets in a comfortable, reclining chair or hammock till noon, when he has his luncheon. After luncheon he is allowed an hour's repose, when he again goes out to remain till 6 p. m. After the evening meal he can stay in the house and enjoy a card game, music or light reading till 8 p. m., when he goes to bed. If properly clothed and wrapped in blankets while sitting out doors the patient will be comfortable in the coldest weather. There is absolutely no danger from colds, bronchitis or pneumonia, as is often supposed from this mode of treatment; in fact, there is less liability to these troubles out of doors than in the house.

PHYSIOLOGIC EFFECTS OF REST.

In rest in the open air we possess a means that has no equal for the good and lasting influence it exerts on the fever of tuberculosis. Agglutinins, anti-toxic and bacteriolytic substances are formed much faster in tuberculosis with the patient at rest than when he is active, which accounts for the decline in the temperature and the diminished activity of the bacilli at the site of the local lesion. Given a case with fever that does not show a decided decline after a period of two weeks of rest, the prognosis is bad. The pulse soon returns to its normal force and frequency, when the patient is at rest. The red blood corpuscles and hemoglobin increase, and in cases with marked anemic onset this increase is often very rapid. The appetite, nutrition and digestion improve; the nitrogen absorption and retention are both increased. The patient experiences a sense of well-being; he feels stronger and better in every way and despair gives way to hope as each day sees a step gained toward vigor and health. The weight rapidly increases.

It is generally supposed that forced feeding is contraindicated in the rest cure, that the patient will suffer from autointoxication, anorexia, diarrhea and loss of appetite, as he certainly would in health, but in tuberculosis the opposite is the case. When active exercise is taken the patient does suffer from autointoxication and fatigue toxins, which evidence themselves by febrile phenomena. At the present time I have a patient, 25 years old, with extensive disease of the right lung, who is taking 36 raw eggs and a gallon of milk, besides his three regular meals, each day. He has gained 47 pounds in weight in three months. During all this time he has been kept perfectly quiet. He has suffered no inconvenience from this enormous quantity of food and says he feels perfectly well. His fever has gone, cough and expectoration are much less, and with proper care I have no doubt but that he will entirely recover.

GENERAL REMARKS.

A safe rule to follow is to keep the patient quiet till every sign and symptom of the disease have disappeared and as long afterward as circumstances and necessity will permit. In the light of my experience in the treatment of this malady exercise has no place in the treatment, and should be allowed only when the arrest or cure has been attained and not then with the expectation of doing any good, but with the desire that the patient return to the full enjoyment of life. The advocates of active exercise say that it improves nutrition, hastens the healing of the local lesion and acts as a hardening process, but is

this the case? As a rule, patients at absolute rest in the open air will take more food, digest it better and gain flesh and strength faster than similar patients taking exercise. The action of exercise on the local process according to Bernheim, is an active congestion in the region of the tuberculous focus and often new tears in the old adhesions, mobilization of the bacilli, thoracic pain and sometimes hemorrhage or the unexpected occurrence of the pneumothorax. Osler says: "Make the patient fat and the local disease will take care of itself."

In the light of this statement, which is certainly correct, why should we prescribe forced feeding for a patient and then allow him to use all his energy taking exercise instead of in combating the disease? How often we see patients who have been kept quiet in the open air and have grown fat and healthy looking, with a marked decrease or complete cessation of all their symptoms, relapse when they begin to take active exercise. This very fact is the great bar to the successful treatment of the patients of the working classes; necessity compels them to return to their work, which means exercise and often a lighting up of their old trouble. Exercise from choice has no place in the treatment of pulmonary tuberculosis and is permissible only when necessity demands it.

It can be urged against this rather radical course that the moral effect on the patients will be bad and that some freedom should be allowed in the way of outdoor games, such as baseball or golf. This can be overcome by explaining to the patient that with absolute quietude that time occupied in effecting a cure will be much shorter, the results more permanent, and that there will be less liability to such accidents as hemorrhage or secondary infections. A good moral effect can be produced by short carriage rides, card games and light reading. Tuberculous patients are very susceptible to encouragement and argument, and with a little explanation in regard to rest and exercise they soon fall into the "rest habit," and will be loath to begin exercise when permitted by the medical attendant. I have never known rest, no difference how prolonged, to do any harm, while exercise brings more tuberculous patients to grief than all other things combined.

THE VALUE OF HYDROTHERAPY IN THE TREATMENT OF EPILEPSY.*

GUY HINSDALE, A.M., M.D.
HOT SPRINGS, VA.

The position of hydrotherapy in the treatment of epilepsy may be considered as a means of cure; an auxiliary method of treatment; a method making it possible to administer considerably larger doses of bromids than usual; a method rendering it possible to reduce the dose of bromid to a minimum; and, finally, as an excellent hygienic measure favoring the action of the skin and improving the general tone.

As a cure *per se* hydrotherapy is probably like all other medicines—it has been tried and found wanting. Notwithstanding the fact that the means employed consist of water, cold, warm or hot, in tubs, douches, sprays, vapor baths, hot air baths and compresses, a method permitting the widest variations in the form of treatment, it probably has rarely, if ever, cured, in and of itself, a case of genuine epilepsy. Cases have been reported

cured, as is so frequently done after surgical methods such as trephining, but further investigation shows that there has been some error in diagnosis, the case being one of hysteria, or that relapses have occurred.

A few French authors have advocated hydrotherapy since Fleury in 1875 published his treatise¹ on the subject. Winternitz and his school have declared that hydrotherapy in epilepsy employed exclusively produces no effect. On the other hand, some of the more recent German publications look on the subject more favorably. Schweinburg in his recent work² cites a patient, a college student, who took under his direction "half baths" for a year and later entered official life and has remained well for sixteen years. Schweinburg says that this is not the only similar case in his experience, but, of course, he pays very strict attention to the diet, and he notes that when the epileptic is ordered a combination of hydrotherapy with a rigid dietary the epileptic attacks diminish with very little bromid, so that there is a reduction from six to eight grams daily to one or two grams. Long intervals free from attacks are obtained and a general improvement in the mental and physical condition is noted.

The procedure adopted at first was the half bath of 27.5 C. (81.5 F.) to 30 C. (86 F.), with affusions and strong rubbing for five or six minutes once or twice daily. Before applying water of lower temperature or more energetic measures such as douches, slapping or in using the high temperatures there should be caution, for attacks have occurred during the application of extreme temperatures.³ Wet packs, foot baths and cold compresses to the head are useful after severe attacks. No unpleasant results have been noted, no increase in the number of attacks, even in the most unfavorable cases. Schweinburg considers the combined hydrotherapeutic and dietetic method more as a school for patients who thus learn the principles and practice of hygienic treatment to be followed during the coming years.

Pick maintains much the same position in holding that with hydrotherapy we can employ considerably smaller doses of the bromid than when the latter is given alone. Pick employs during the interval between the attacks the so-called half baths of 27 C. (80.5 F.) to 30 C. (86 F.) and of eight to fifteen minutes duration, as well as sitz baths and trunk compresses or the so-called "Neptune's Girdle." Without necessarily the expectation of a cure he uses systematic hydrotherapy so as to promote the action of the skin or as a mode of treatment auxiliary to other measures.

Binswanger advises in this connection a mild hydrotherapy as usually adopted in the general treatment of neurasthenia; also a daily bath, using water gradually cooled to 15 C. (59 F.), indifferent baths two or three times a week with or without the addition of salt or affusions at 20 C. (68 F.). For young and vigorous subjects he advises cool or cold baths of only a few minutes duration. The temperature should be about 24 C. (75 F.) and gradually cooled, according to the state of health of the patient, to 20 C. (68 F.). Binswanger employs these cool baths especially during the first weeks of the use of Flechsig's treatment.

Ehlenberg recognizes in such measures a wide applicability to raising nutrition and improving the skin, al-

most never disappointing, especially in bad cases of bromism. He uses the spinal ice bag when the methods referred to are not permissible.

Matthes⁴ of Jena takes a very conservative position, making use of hydrotherapy only for a good effect on the skin and an increase of the bodily vigor. This is especially necessary during treatment with bromids and should be adopted so as to obviate as much as possible bromid acne. He uses indifferent baths, that is, at about the body temperature, three times a week and also the more refreshing procedures such as the wet sheet rub (abreibung) and half baths. During the attack treatment with ice caps, stimulating compresses or diverting methods, such as slapping the feet with cold cloths, are useless. He holds that the action of hydrotherapy in epilepsy, whether for preventing attacks or rendering them less frequent, rests on a very slender foundation.

As we all know, bromids often do harm in the treatment of epilepsy. In any large institution such as Sonyea, where 2,000 cases have been treated and carefully studied, this difficulty is well recognized and the average dose employed is about one gram daily. At Bielefeld the dose is about three grams daily. In France rather larger doses are given; Feré and Jarnot have used from twelve to sixteen grams daily in special cases.

Among the earlier symptoms are acne and physical depression; later a decidedly weakened action of the heart amounting to chronic cardiac asthenia; ptosis of the lids and even inability to walk. In extreme cases in which the dose is very large or the patient unusually impressed by the drug there may be disturbances of memory and suicidal or homicidal tendencies. I have seen an epileptic patient in an outburst of passion at a fancied wrong, attack a resident physician with great violence. Such cases have been recorded by Echeverria,⁵ Weir Mitchell and others.

We would, therefore, welcome any method that will enable us to use these larger doses with safety to the skin and to the mental equilibrium. Just as warm baths and other hydrotherapeutic procedures undoubtedly enable us to administer potassium iodid in large doses with safety and increased efficacy so I believe that with the help of baths the bromids will be better borne.

As to any ill effects from the use of baths I have knowledge of only one instance in which an attack occurred while bathing. This was in the case of a young man who for nearly a fortnight had been swimming and diving in a large enclosed swimming pool. Although in water beyond his depth, he had his convulsion at the surface and was soon brought by friends to a place of safety. The temperature of the water was about 78 F. and there is no reason to believe that the water had any special influence in causing the attack.

In America attention was first called to the value of hydrotherapy in epilepsy by Dr. Simon Baruch and later by the late Dr. G. W. Foster, one of the physicians at the Government Hospital for the Insane at Washington.⁶ The measures employed were the drip sheet, wet packs and douches. By these means bromid acne was either prevented or relieved and the general tone of the patients was improved. The number of attacks in twelve patients was reduced by about 40 per cent. Since this report was issued no further records have been kept, and I am informed that few patients, if any, received

any permanent benefit, and this treatment is not now used to any extent in this class of cases.

At the Pennsylvania Epileptic Hospital and Colony Farm the patients receive daily showers and a tepid tub bath once or twice a week. These are more for hygienic than for therapeutic purposes.

At the Glenmary Sanitarium at Owego, New York, baths are given only for personal cleanliness.

At the Craig Colony for Epileptics at Sonyea, New York, complete hydrotherapeutic apparatus has just been installed. Systematic treatment will no doubt be adopted under the most favorable circumstances, as these patients receive a minimum dose of bromid, about one gram daily, and are under an excellent hygienic régime. We shall look with interest to the results that will be obtained when the large number of patients at the colony have been treated after an approved method.

At the Glenwood Sanitarium at Dansville, New York, Dr. J. W. Wherry writes me that some years ago he gave considerable attention to hydrotherapeutic methods in the treatment of epilepsy, but he is not able to say that he noticed any direct effect on the epileptic condition. Since then he has discarded the measure excepting when indicated on general principles without reference to the epileptic condition itself. In a letter to me Dr. Wherry remarks very truly: "Whatever benefits the individual is an aid in the treatment of epilepsy. Some epileptics, like some other people, would be benefited by the employment of hydrotherapy; others would not."

In private practice difficulties are encountered in carrying on systematic treatment of this description. Daily treatment for several months would be required, and, of course, unbounded patience and hope are demanded of both physician and patient. The usual experience of outdoor clinics is that as patients improve their visits are more infrequent, but not rarely we find faithful ones who report regularly for years.

We would naturally expect that in focal or traumatic epilepsy less advantage would be derived than in cases of so-called idiopathic epilepsy, alcoholic epilepsy, psychic epilepsy, or in cases arising from intestinal intoxication or obscure metabolic changes. In such cases the free use of water inside and out ought certainly to be given a prominent place in any plan of treatment that may be adopted.

TEXT COTTAGES FOR CONSUMPTIVES.

E. FLETCHER INGALS, M.D.

AND

JOHN M. DODSON, M.D.

CHICAGO.

A recent visit to New Mexico afforded us an opportunity to inspect the tent cottages for consumptives designed by Dr. W. T. Brown, the superintendent of the Valmora Ranch at Watrous, N. M.

These cottages present such a distinct advance in design and construction for their purpose that a detailed description seems worth the while. It may be well to preface the description by a brief statement of the conditions which such structures should fulfill. While the great desideratum is provision for a practically out-of-door existence for these patients, both by day and by night, there is no reason why this should be secured by large sacrifice of the chief comforts and conveniences to which they have been accustomed. The canvas tent, if properly made and set up, makes a very comfortable home in pleasant weather, but it is practically impossible to construct a tent in such a way as

⁴ Max Matthes: *Lehrbuch d. klin. Hydrotherapie*, Jena, 2d Ed., 1901.

⁵ Manuel Gonzales Echeverria: *Amer. Jour. Insanity*, 1873-4, vol. X.

⁶ Report of the U. S. Government Hospital for the Insane, 1898; also *Amer. Jour. Insanity*, No. 4, 1899.

to afford adequate protection against severe rain, hail or snow storms, high winds and extremes of temperature. It can not be readily equipped with sanitary conveniences, nor does it provide for a freer circulation of air than a more substantial structure, which assures the desired protection.

The cottages are constructed with one or two rooms. They are arranged on either side of and facing the lawn in front of the main building and are exposed on all sides. Each single-room cottage (Fig. 1), is 12x12 feet in area, is constructed of a framework of sixteen 2x4 uprights resting on 4x6 sills, which are supported on a stone foundation (Fig. 2). The five floor joists of 2x6 timbers support the floor of five-inch flooring. The sides are of five-inch drop siding to the height of three and one-half feet, while the remaining three and one-half feet of each side consists of twelve-ounce duck and three windows—one in front and one on each side—each window a six-pane 3x3 1/3 feet high, sliding laterally. The canvas sides, stretched on frames of 1x3-inch pine, a little larger than the windows, are so arranged as to provide five sections, one on each

interior, in a restful light brown, with the floor a light slate. With the canvas sides and windows closed and a light fire in the stove these cottages may be made perfectly comfortable for retiring at night and dressing in the morning. At night, when the occupant has prepared for bed, the windows and canvas sides are opened—from the inside of the cottage the work of but a moment—

Fig. 1.—Single cottage.

side and three at the back of the cottage, which are hinged at the top and opened by pushing out the bottom of the frame by a rod projecting through a hole in the wall just below the screened opening, so arranged that the frame is held firmly at any angle by a cord, which is also fastened from the inside. The door, 2 1/2 x 6 1/2 feet, is at one side of the front elevation.

The gable roof, with a pitch of 1/3, is of cedar shingles above, and between this and the ceiling of stretched canvas below is an air space of four inches, opening by a series of large augur holes under the eaves and similar holes in the gable. These may be closed by a slide, so that this space may be made, in cold weather, a dead-air space, the best of insulators, while in warm weather it may be opened and the air allowed to circulate freely between the ceiling and the roof. Each cottage has a porcelain lavatory with running water and is furnished with a metal bedstead, the best of mattresses and bedding, a dresser, clothes press, table, chairs and a small stove.

The cottages are neatly painted a light slate color, with lighter trimmings; the roof, in Indian red; the

Fig. 2.—Single cottage, rear view.

and he is at once practically out of doors, though perfectly protected from the severest storms. All of the openings are thoroughly protected from flies, etc., by wire screens.

The double cottages are similar in construction, excepting as to dimensions, which are 12x24 feet, making each room of the same size as that of the single cottage (Fig. 3).

Fig. 3.—Double cottage.

The location of such cottages is important. Their site should be on ground affording perfect drainage, and the outlook should be as attractive as it is possible to secure.

Dr. Brown generously offers to supply the exact plans and specifications of this improved Valmora tent cottage to any physician desiring to construct one.

THE OPERATIVE TREATMENT OF FRACTURES.

JAMES A. KELLY, M.D.
PHILADELPHIA.

(Concluded from page 108.)

THE AFTER-TREATMENT OF FRACTURES TREATED BY THE ABOVE METHODS.

After the operation the patient's temperature should be carefully recorded, and on the first indication of sepsis—rise in temperature combined with localized pain of a dull, throbbing character—a window should be cut in the plaster-of-paris dressing at the site of the operation and the wound inspected. If sepsis is present, it may be recognized by the usual signs. The skin sutures should then be removed and adequate drainage instituted. Irrigation with a mild solution of bichlorid of mercury or a normal salt solution, should be performed twice daily. Sepsis should not occur with any more frequency than in operations on other parts of the body. When the subjective signs show that healing by first intention is taking place, the dressing should not be disturbed until the seventh to the tenth day, when a window may be cut in the plaster-of-paris dressing, and the skin sutures removed. The subsequent treatment consists in the adoption of passive motion and massage as soon as union has taken place. As a rule, the period of disability will be much shorter, splints or a plaster-of-paris dressing should be worn a shorter time, and active motion and use of the part may be indulged in earlier than in similar cases treated by non-operative methods.

SUMMARY OF CASES.

CASE 1.—*Closed Fracture of the Femur.*—J. H. (B. C. II., Surgical Records B., vol. 420, p. 58), service of Dr. Bolles. Admitted June 7, 1904. Patient was thrown out of a window to the ground, a distance of about 20 feet. Unconscious for several hours.

Physical Examination.—Left leg at junction of middle and lower thirds presented a fracture of tibia and fibula. The right femur presents crepitus, abnormal mobility and deformity about the middle, with the lower end of the upper fragment almost piercing the skin.

The patient was etherized at time of admission, and the fracture of the left tibia and fibula and immobilized in a plaster-of-paris dressing from the toes to the groin. Repeated attempts to reduce the fracture of the right femur were fruitless. As no permission was obtained to operate, a modified Buck's extension apparatus was applied.

Operation.—June 18. Eleven days after entrance. Dr. Kelly. Ether anesthesia. An incision about four inches in length was made on the anterior surface of the right thigh at the seat of the fracture. The fractured ends were exposed. Considerable muscular tissue was found between fragments. Ends of fractured bone freed and, by manipulation and traction, approximated and remained locked. No bone suture used. The wound was closed in layer sutures of plain catgut and the skin by a subcuticular silkworm gut suture. A modified Buck's extension apparatus applied.

June 28: Skin suture removed. Wound entirely healed. Fragments in good position. Fair union.

July 27: Tibia shows firm union. Good union in femur.

August 8: Union of right femur firm. All apparatus omitted. Seven weeks after the operation.

August 26: Discharged. Relieved. Union at seat of fractures firm. No deformity. No shortening. Patient went out, using crutches, at the end of nine weeks. X-ray photograph showed the position of the fractured ends to be very good.

CASE 2.—*Closed Fracture of the Tibia.*—G. C. (B. C. II., Surgical Records B., vol. 411, p. 91).—Admitted Feb. 6, 1904, to

the service of Dr. Cushing. Patient slipped on a cover of a coal hole and fell heavily on ankle.

Physical Examination.—Right leg, from ankle to knee, markedly swollen, the skin is covered on its anterior surface with 5 to 6 blebs, crepitus, abnormal mobility, deformity and fracture of the tibia at the junction of the middle and lower thirds. Shortening $\frac{3}{4}$ to $1\frac{1}{2}$ inches. Marked overriding of the fragments. A small abrasion about the size of a silver dollar on inner anterior surface of leg about middle. On account of abrasion, immediate operation was not advised. Attempts made to reduce fragments with anesthesia were fruitless. Several forms of apparatus were devised to produce continued extension on the lower fragment without any result. At the end of three weeks the probability of non-union, deformity and shortening were explained to the patient and an operation advised.

Operation.—March 1, 1904. Dr. Monks and Dr. Kelly. Ether anesthesia. Vertical incision six inches long at seat of fracture. Ends of fragments exposed. Marked deformity of fragments; the upper end of the lower fragment projected backward, upward and inward into muscles of the back of the leg. Moderate amount of fibrous tissue between fragments. It was found impossible to secure approximation, so resection of the ends of both fragments was performed *in situ* with a chisel. All fibrous tissue removed. After approximation, internal fixation was secured with six interrupted chromicized catgut sutures. Periosteum and soft parts united by interrupted catgut sutures, and the skin by interrupted silkworm gut sutures. No drainage. A dry gauze dressing was applied to the wound and immobilization secured by a plaster-of-paris dressing from the toes to the groin.

March 19: No subjective symptoms since operation. Window cut in plaster, wound found to have healed by first intention. Skin sutures removed.

April 16: Plaster dressing removed. Union found to be firm. No deformity. Shortening $\frac{1}{4}$ of an inch. Second plaster-of-paris dressing and patient discharged, using crutches.

May 20: Plaster dressing removed. Union solid. No deformity. Massage, passive and active motion recommended. Advised to use crutches until they can be discarded. Figures 1 and 2 are from x-ray photographs taken before the operation. Figures 3 and 4 are from x-ray photographs taken four weeks after the operation.

CASE 3.—*Closed Fractures of the Tibia and Fibula.*—T. C. (B. C. II., Surgical Records, B., vol. 416, p. 82).—Admitted March 18, 1904, to the service of Dr. Cushing. During a quarrel the patient was thrown to the ground, injuring his right leg.

Physical Examination.—Considerable swelling and ecchymosis of entire right leg. Several blebs on anterior surface. Shortening $\frac{3}{4}$ of an inch. Crepitus, abnormal mobility and deformity present at middle of tibia, line of fracture probably oblique. Fracture of fibula at junction of middle and upper thirds. X-ray photograph shows an oblique fracture of tibia four inches above the internal malleolus. The upper end of the lower fragment of the tibia is displaced inward, backward and upward. Manipulation under anesthesia failed to reduce the fracture.

Operation.—April 6, 1904. Dr. Kelly. Ether anesthesia. The seat of fracture was exposed under aseptic precautions, and all bleeding controlled. Impossible to secure approximation on account of union having taken place at the seat of fracture of the fibula. An incision was then made over the seat of fracture of the tibia and the union divided. The ends of the fragments of the tibia then approximated and sutured by five interrupted chromicized catgut sutures. The wound closed as usual without drainage. Immobilization from toes to groin in a plaster-of-paris dressing.

May 6: Wound healed by primary union. Sutures removed at the end of ten days.

May 17: Plaster removed. Union firm. No deformity. No shortening. A fresh plaster dressing applied, and patient was discharged, using crutches, six weeks after the operation. Figures 5 and 6 show the x-ray photographs taken six weeks after the operation.

CASE 4.—*Ununited Fracture of the Femur*.—J. G. (B. C. II., Surgical Records, B., vol. 414, p. 230).—Admitted to hospital Jan. 20, 1903, with a fracture of the left femur near the middle. For a period of three months a modified Buck's extension apparatus was applied without any union taking place. At the end of this time, patient, having refused operation, left the hospital. Eight months after the injury, a resection of the ends of the fragments was performed by a private physician, and silver wire was used to secure approximation. The wound became infected, the wire broke and non-union resulted. Patient re-entered the hospital Feb. 25, 1904. At this time the examination showed a fracture of the left femur about the middle. Marked overriding of the fragments and deformity. After complete extension the shortening was $1\frac{1}{2}$ inches. Scar on external surface of the thigh at the seat of the fracture.

Operation.—March 3, 1904. Dr. Monks, Dr. Kelly. Ether anesthesia. An incision was made on the external surface of the thigh and carried down through dense fibrous tissue to the seat of fracture. A condition of pseudarthrosis was found. The silver-wire suture from the previous operation was found to be broken and was removed. The ends of both fragments were resected and sutured together with heavy chromicized catgut, and the wound closed without drainage. A plaster-of-paris bandage, extending from the toes to the chest, secured immobilization. Following the operation, sepsis occurred, and required removal of the skin sutures for drainage. No union resulted at the end of seven weeks, when another attempt to secure union was made. The ends of the bone were freshened and united with three silver-wire sutures. Drainage was instituted and a plaster dressing applied as before. At the end of six weeks, as no union had occurred, the patient demanded amputation, which was performed two inches above the seat of fracture, Aug. 5, 1904, by Dr. Monks.

Sept. 3: The patient was discharged, with a granulating stump. One month later the patient returned to the hospital and was operated on for advanced carcinoma of the pylorus, and, after lingering several weeks, died. Figure 7 is an x-ray photograph showing the broken silver wire which failed to secure approximation. The introduction of sepsis at the first operation probably predisposed to reinfection at each subsequent operation. The presence of carcinoma of the pylorus and its consequent cachexia may have had some influence in the production of non-union.

CASE 5.—*Closed Fracture of the Femur*.—J. B. (B. C. II., Surgical Records, B., vol. 414, p. 172).—Admitted Feb. 16, 1904, to the service of Dr. Cushing. While patient was assisting in the moving of a heavy wooden tank, it fell on his legs, totally disabling him. Patient markedly shocked at the time of injury.

Physical Examination.—Shows a fracture of the right femur about four inches above the knee-joint. The upper end of the lower fragment is displaced upward and backward. The knee joint is considerably distended with fluid. In addition, there is a fracture of the left tibia about two inches from the upper end and a fracture of the internal malleolus of the same bone. On account of the shock from which the patient did not entirely recover for two weeks, the fractures were placed in temporary splints, and no attempts were made at reduction.

Operation.—March 7, 1904. Dr. Monks, Dr. Kelly. Ether anesthesia. Attempts were made three days ago to reduce the fracture of the femur with anesthesia, without success. To-day, through two lateral incisions on the inner and outer surfaces of the thigh at the seat of fracture, the fragments were exposed. Considerable amount of muscular tissue found between the fragments. By means of extension, abduction and adduction the fractured ends were approximated, locked in place by their irregular surfaces, and retention was secured by means of two heavy chromicized catgut sutures passed through the diameter of the fragments. The wounds were closed in layers without drainage, and a plaster-of-paris dressing was applied from the toes to the chest, securing complete immobilization. Reduction of the fractures of the left tibia was readily accomplished and immobilization secured by plaster-of-paris dressings.

March 24: No subjective symptoms occurred since the operation. The skin sutures were removed to-day.

April 18: Moderate-sized callus and firm union at the seat of fracture of the femur.

May 5: Plaster-of-paris dressing removed. No shortening; no deformity. Firm union. No further splint.

May 1: Up in a wheel chair.

May 13: Discharged, using crutches.

CASE 6.—*Closed Fracture of the Tibia*.—J. L. (B. C. II., Surgical Records, B., vol. 416, p. 86).—Admitted March 19, 1904, to the service of Dr. Cushing. Patient tripped over a piece of carpet, turning on ankle, eleven days before admission. Treated by private physician since the time of the accident.

Physical Examination.—The right leg is swollen from the toes to just below the knee. Marked tenderness, abnormal mobility and crepitus about three inches above the tip of the internal malleolus. Apparently some overriding of the fragments, the upper end of the lower fragment being displaced upward, outward and backward. Attempts under anesthesia to secure reduction of the fracture were not followed by success.

Operation.—March 30, 1904. Dr. Monks, Dr. Kelly. Ether anesthesia. The seat of fracture was exposed through an anterior incision. The fragments were found displaced, the upper end of the lower fragment being displaced upward, backward and outward. Approximation of the fragments was impossible on account of the overriding and the presence of fibrous tissue. The latter was removed, tenotomy of the tendo Achilles, and osteotomy of the fibula four inches above the external malleolus were performed, which permitted of approximation, after a small portion of either fragment had been resected with a chisel. Internal fixation secured by means of heavy chromicized catgut. The wound was closed in the usual way and without drainage. Immobilization was secured by means of a plaster-of-paris dressing applied from the toes to the groin.

April 16: There have been no subjective symptoms since the operation. A window was cut in the plaster and the wound was found to have healed by primary union. Skin sutures were removed. Up and about on crutches at the end of four weeks.

May 3: Thirty-four days after the operation the patient was discharged with a light plaster and using crutches. Union was solid. No deformity present at the seat of the fracture. Shortening $\frac{1}{4}$ of an inch. Figure 8 shows the condition present before the operation, and Figure 9 the results obtained by the operation.

CASE 7.—*Ununited Fractures of the Humerus and of the Radius*.—P. S. (B. C. II., Surgical Records, B., vol. 419, p. 106).—Admitted Nov. 24, 1903, to the service of Dr. Bolles. Patient fell off the back of a wagon, sustaining a compound fracture of the left humerus about three inches from its head and a closed fracture of the right radius at its middle. At the time of admission the compound fracture of the left humerus was thoroughly cleaned, the edges of the bone were not sutured and drainage was introduced. A moderate degree of sepsis occurred, which was afterward followed by non-union at the seat of fracture. After admission to the hospital the fracture of the right radius was reduced, and the entire forearm and arm immobilized in a plaster-of-paris dressing. Non-union also resulted here.

Operation.—Feb. 5, 1904. Eleven weeks after the injury. Dr. Monks, Dr. Kelly. Ether anesthesia. An incision was made over the seat of fracture of the right radius, and the fragments exposed. Some interposition of muscular tissue present between the fractured ends of the bone. This was removed, the ends freshened and internal fixation secured by medium chromicized catgut. The wound was closed without drainage, and immobilization was secured by a plaster-of-paris dressing from the hand to the upper arm.

Operation.—March 29, 1904. Dr. Monks, Dr. Kelly. Ether anesthesia. As non-union had resulted in the humerus, the seat of fracture was exposed by a vertical incision at the inferior edge of the deltoid muscle. The fractured ends were found to be separated by muscular and fibrous tissue. This was removed and the fractured ends of the bone were carried through the wound and resected. Internal fixation was secured by means of heavy chromicized catgut, and, on account of sepsis having taken place, when the fracture was compound,

drainage was instituted. Immobilization was secured by splints and bandages. Drainage was removed at the end of two weeks and union was firm here and also in the radius at the end of eight to ten weeks. Figure 10 is the x-ray photograph taken before the operation, and Figure 11 the result obtained after operation.

CASE 8.—*Ununited Fracture of the Radius*.—H. D. (B. C. II., Surgical Records, B., vol. 402, p. 60).—Admitted June 23, 1903, to the service of Dr. Cushing. The patient was struck on the right forearm by a heavy beam.

Physical Examination.—Fracture of the right radius near its middle, abnormal mobility, crepitus and deformity being present, and over the seat of fracture there is an irregular wound.

After admission the wound was thoroughly irrigated and cleaned. The incision was enlarged and the fracture was found to be irregularly transverse, the lower fragment being displaced upward and toward the ulna. After considerable difficulty the fragments were locked together and the wound closed in layers. Drainage, with rubber tissue, used, which was removed at the end of two days. Immobilization with plaster-of-paris. The wound healed by primary union, and the stiffliness were removed at the end of seven days. At the end of three months no union had taken place and it was determined to suture the fractured ends together.

Operation.—Sept. 11, 1903. Dr. Hubbard. Ether anesthesia. An incision about three inches in length was made over the radius and the fractured ends exposed. The upper end of the lower fragment was found to be displaced upward and toward the ulna, as shown in Figure 12. Fibrous tissue was present between the fragments. This was removed by a curette and gouge, and the ends of the fragments resected. The approximated ends were then held together with a silver-wire suture, as shown in Figure 13. The wound was closed without drainage, and immobilization secured by means of a plaster-of-paris dressing applied from the hand to the upper arm. The wound healed by primary union, and the skin sutures were removed on the eighth day.

October 23: Forty-two days after the operation the patient was discharged, carrying the forearm in a sling. Union fairly firm, slight bowing toward the ulna at the seat of fracture. Pronation and supination good. Movements at the elbow and wrist joints slightly limited.

Figure 12 shows the condition before, and Figure 13 after, the operation.

CASE 9.—*Compound Fracture of the Femur*.—H. S. (B. C. II., Surgical Records, B., vol. 408, p. 176).—Admitted Oct. 27, 1903, to the service of Dr. Bolles. Patient caught foot in wheel of a team while hooking a ride.

Physical Examination.—Shows a fracture of right femur at the junction of the middle and lower thirds; abnormal mobility, deformity, crepitus and shortening of 1 inch present. Just below the internal condyle there is a transverse lacerated wound about six inches long, which communicates with the seat of the fracture.

Operation.—Dr. Kelly. Ether anesthesia. The wound was thoroughly irrigated and cleaned, and by manipulation the fragments were approximated. The skin wound was closed by interrupted silk-worm gut sutures, except at the point for drainage. Immobilization was secured by a plaster-of-paris spica applied from the toes to the chest, and extension applied to the lower end of the plaster. At the end of two weeks the external wound had entirely healed. On account of shrinkage of the soft parts and slipping of the plaster-of-paris spica, overriding of the fragments and shortening occurred. This was corrected Dec. 10, 1903, and a modified Buck's extension apparatus applied. Good union, without shortening or deformity, subsequently occurred.

CASE 10.—*Compound Pott's Fracture*.—J. T. (B. C. II., Surgical Records, B., vol. 414, p. 108).—Admitted Feb. 8, 1901, to the service of Dr. Cushing. Patient fell from a fire escape, a distance of fifteen to twenty feet, turning on ankle, and receiving a compound fracture, the end of the bone protruding through the skin.

Physical Examination.—Swelling of the lower third of left leg over the internal malleolus. An irregular, jagged wound, size of 10 cent piece, over the internal malleolus, exposes a

fracture of the internal malleolus. Fracture of the fibula $1\frac{1}{2}$ inches above the external malleolus present, with marked outward dislocation of the foot.

Operation.—Dr. Kelly. Ether anesthesia. The wound, which extended into the ankle joint, was thoroughly irrigated with normal salt solution, and small portions of tissue, into which dirt was ground, were cut away. The fracture was reduced and the torn periosteum united with medium-sized chromicized catgut sutures. The foot was held in its normal position by an assistant until the plaster-of-paris dressing was applied. The wound was closed by interrupted silkworm gut sutures, except at a point of drainage. Drainage was dispensed with at the end of three days, and the sutures were removed at the end of ten days, primary union having taken place.

April 6: Union firm. Moderate-sized callus. No deformity. Foot in good position. Movement of ankle joint free. Discharged, wearing a light plaster and using crutches.

CASE 11.—*Compound Fracture of the Humerus*.—J. C. (B. C. II., Surgical Records, B., vol. 414, p. 44).—Admitted Jan. 30, 1904, to the service of Dr. Bolles. The patient, a boy of 9 years, was injured by a sled passing over his left arm.

Physical Examination.—Shows a compound fracture of the left humerus about $1\frac{1}{2}$ inches above the condyles, the line of fracture being transverse. Through a wound about one inch in length on the inner surface of the arm, the seat of fracture could be seen.

Operation.—Jan. 31, 1904. Dr. Kelly. Ether anesthesia. The arm was thoroughly cleaned, the wound irrigated with normal salt solution and enlarged and the seat of fracture exposed. The line of fracture was irregularly transverse. A counter incision was then made on the external surface of the arm. The fragments were approximated and held together by two interrupted chromicized catgut (No. 3) sutures passed through the entire diameter of the bone. The wounds were sutured in the usual manner without drainage. The part was immobilized in splints and a swathe.

The wounds healed by primary union, the stitches were removed on the tenth day, and on February 17 the patient was discharged with fairly firm union, and no deformity. Further treatment was continued in the out-patient department. Figure 14 is from the x-ray photograph taken five weeks after the operation.

CASE 12.—*Compound Fractures of the Tibia and Fibula*.—D. D. (B. C. II., Surgical Records, B., vol. 412, p. 158).—Admitted Jan. 6, 1904, to the service of Dr. Bolles. The patient was injured by the explosion of a water-back of a range.

Physical Examination.—Shows considerable swelling and ecchymosis of entire left leg. On the outer surface of left leg about its middle is an irregular lacerated wound about $1\frac{1}{2}$ inches long, and on the anterior surface there is a similar wound. About the middle of the left tibia there is an oblique fracture with marked overriding of the fragments and displacement of the fractured ends. A fracture of the left fibula about its middle is also present. Surrounding the wounds there is considerable destruction of the soft parts. In addition the patient had marked synovitis of the right knee joint and lateral mobility.

Operation.—Shortly after entrance. Dr. Kelly. Ether anesthesia. The skin was rendered aseptic as usual, and the wounds were thoroughly irrigated with normal salt solution and enlarged, disclosing an oblique fracture of the fibula. Both fractures were reduced and approximation remained good without suturing the fragments. The wounds were closed in layer sutures and drainage used in both wounds. Immobilization secured with a plaster-of-paris dressing from the toes to the groin, and a window was cut in the plaster for subsequent observation.

Following the operation, there was considerable sloughing of the skin and superficial fascia, exposing the lower end of the upper fragment of the tibia for a distance of two inches. Extension was applied to the foot by means of a special Cabot splint and plaster dressing, so that the fragments were always in good position. The wound gradually closed, excepting for a small area over a portion of the upper fragment of bone, which became necrosed and subsequently separated. At the end of three months the wound had entirely closed and there was be-

gining union at the seat of fracture, with shortening of about $\frac{1}{2}$ inch. The patient was then discharged to the out-patient department, wearing a plaster-of-paris dressing and using crutches. Solid union subsequently occurred, and the patient recovered with a sound limb which was not deformed.

CASE 13.—*Compound Fractures of the Tibia and Fibula*.—F. K. (B. C. H., Surgical Records, B., vol. 418, p. 160).—Admitted May 12, 1904, to the service of Dr. Cushing. The patient, while running for a car, slipped and fell, with his leg doubling up under him.

Physical Examination.—On the outer surface of the left leg, at the junction of the middle and lower thirds, there is an irregular lacerated wound about two inches in length, leading down to a fracture of the fibula. At a position about one inch above the fracture of the fibula there is an oblique fracture of the tibia. There is marked deformity and overriding of the fragments of both bones.

Operation.—Dr. Kelly. Ether anesthesia. The skin was prepared in the usual manner and the wound thoroughly irrigated with normal salt solution and enlarged. The seats of fracture were exposed and reduction of the fragments accomplished without difficulty. Interlocking of the fragments obviated internal fixation with catgut. On account of the apparent cleanliness of the wound it was closed in the usual manner without drainage and immobilization secured with a plaster-of-paris dressing applied from the toes to the groin.

Eight days after the operation the wound was inspected, and primary union had taken place. The skin sutures were then removed.

June 20.—Thirty-nine days after the operation, the plaster-of-paris dressing was removed and firm union was found to be present. The position was good, there was no shortening and no deformity. A fresh plaster-of-paris dressing was applied, and the patient discharged, with crutches, to the out-patient department.

CASE 14.—*Compound Fractures of Tibia and Fibula*.—P. G., 37 years (B. C. H., Relief Station Records, vol. 6, p. 151).—Admitted March 18, 1903, to the service of Dr. Bolles. The patient, while intoxicated, fell off a moving train, and at the time of admission was in a condition of marked shock from loss of blood. The operation was delayed four hours until consent for operation could be obtained.

Physical Examination.—The left leg presents a compound fracture of tibia and fibula. At the junction of the middle and lower thirds, the lower end of the upper fragment projecting through a wound on the inner side of the leg. Considerable hemorrhage had apparently taken place.

Operation.—Dr. Kelly. Ether anesthesia. The part was prepared aseptically in the usual manner and the wound enlarged for exploration. Four bleeding veins were ligated. On exposing the seat of fracture, the lower end of the upper fragment of the tibia was found to be discolored with dirt for a distance of $\frac{3}{4}$ of an inch, so that the involved portion was cut away with rongeur forceps and the fractured ends approximated. Internal fixation was secured by means of two silver-wire sutures and the wound closed in the usual method with drainage. Immobilization was secured by means of a plaster-of-paris dressing applied from the toes to the groin. The patient stood the operation very well, and recovered from the anesthetic, but, in spite of most active stimulation, died on the following day (20 hours after the operation), apparently of shock.

CASE 15.—*Compound Fractures of Radius and Ulna*.—M. R. (B. C. H., Relief Station Records, vol. 6, p. 139).—Admitted March 16, 1903, to the service of Dr. Bolles. The patient was injured by having forearm caught between a belt and pulley.

Physical Examination.—The left forearm present on its posterior surface, at a point between the middle and lower thirds, a transverse lacerated wound about two inches long, which is continued down the forearm at right angles for a further distance of two inches, through which projects the upper ends of the lower fragments of the fractured radius and ulna.

Operation.—Dr. Collins, Dr. Kelly. Ether anesthesia. The forearm was prepared as usual and the wound thoroughly irrigated with normal salt solution. The fractured ends of the radius and ulna, after reduction, were held approximated by

means of silver-wire sutures, and the wound closed in the usual manner with drainage. Immobilization was secured by means of a plaster-of-paris dressing applied from the hand to the upper arm, the hand being in a position midway between pronation and supination, and the elbow at a right angle. The wound healed by primary union, and the skin sutures were removed on the eighth day and the patient discharged to the out-patient department. At the end of seven weeks, union was firm and the fragments had united without deformity, although there remained some limitation of pronation and supination.

CASE 16.—*Compound Fractures of the Tibia and Fibula*.—(St. M. H., Surgical Records, No. 513).—Admitted May 17, 1902, to the service of Dr. H. B. Deaver. The patient was injured by a heavy bar of iron falling on his leg.

Physical Examination.—The left leg presents a compound fracture of the tibia about $2\frac{1}{2}$ inches above the ankle joint. Fibula fractured about the same level. Considerable swelling and ecchymosis of the soft parts present.

Operation.—Dr. Kelly. Ether anesthesia. The leg was thoroughly cleaned as usual, and the wound irrigated with a solution of bichlorid of mercury (1/10000). The wound was then enlarged, exposing a double fracture of the tibia, one line of fracture being transverse and the other oblique, leaving a triangular piece of bone held by periosteum. The fragments were reduced and retained in place with silver-wire sutures. The wound was closed in layers and drainage used. The leg was then immobilized in a plaster-of-paris dressing.

Two days after the operation, subjective signs of sepsis being present, several skin sutures were removed, and irrigation used three times a day. In spite of active treatment, the infection became so severe that amputation below the knee was necessary at the end of three weeks. This failed to prevent the spread of the infection, and, as the knee joint became involved, amputation at the lower third of the thigh was performed seven weeks after the primary operation.

The patient finally recovered and was discharged from the hospital, with a healed stump.

CASE 17.—*Malunion Following Colles' Fracture*.—E. B. (St. M. H., Surgical Records, No. 1149).—Admitted Aug. 8, 1904. The patient fell four weeks before admission, injuring wrist, which she considered a sprain, and which was treated as such by a physician. When I saw the patient, the right hand was markedly abducted, pronation and supination were impossible, the radial arch was entirely absent, and marked deformity of the lower end of the radius was present.

Operation.—Dr. Kelly. Ether anesthesia. The part was prepared as usual, and through an incision $1\frac{1}{2}$ inches in length on the radial side of the forearm, at the seat of fracture, the fragments were exposed. The lower end of the upper fragment was displaced toward the ulna and flexor surface of the forearm, and overriding was present. Fibrous tissue intervened between the fragments. This was removed by a gouge and chisel, and reduction accomplished, the fragments interlocking. The wound was closed in the usual manner, without drainage, and sealed with a collodion dressing. Immobilization was secured with well-padded anterior and posterior splints, the hand being held in marked adduction. Primary union occurred and the skin suture was removed on the seventh day. At the end of three and a half weeks, both splints were dispensed with. Union was firm, deformity was absent, pronation and supination were as good as before the injury.

CASE 18.—*Malunion Following Pott's Fracture*.—J. S. (St. M. H., Surgical Records, No. 469).—Admitted May 23, 1902, to the service of Dr. H. B. Deaver. The patient sustained a Pott's fracture four weeks ago, and at the present time the fragments have united, with deformity. The foot is markedly everted and displaced slightly backward.

Operation.—Dr. Deaver, Dr. Kelly. Ether anesthesia. Through a vertical incision about four inches in length over the fibula, the fragments of the latter were exposed. The fractured ends were displaced and united in this position by fibrous union. The fibrous tissue was removed with a gouge and curette, and the ends of the fragments were freshened with a chisel. No union had occurred between the internal malleolus and the tibia. The fracture was reduced and the fragments of

the tibia united by a silver-wire suture. The wound was closed in the usual manner, without drainage, and immobilization secured with a plaster-of-paris dressing applied from the toes to just below the knee. The skin sutures were removed on the tenth day. Primary union occurred, and three weeks after the operation fairly firm union had taken place, without any deformity resulting. The patient was then discharged to the out-patient department, wearing a plaster-of-paris dressing and using crutches.

CASE 19.—*Malunion Following Pott's Fracture.*—C. G. (St. M. H., Surgical Records, No. 375).—Admitted April 15, 1902, to the service of Dr. H. B. Deaver. The patient slipped, turning on ankle, and sustained a Pott's fracture five months previous to admission. He was treated at another hospital, where the foot and leg were placed in a plaster-of-paris dressing and kept there for six weeks. At the end of this time, marked deformity had occurred. On admission, the right foot was markedly everted and the ankle widened.

Operation.—Dr. Deaver, Dr. Kelly. Ether anesthesia. The fragments of the fibula and tibia were exposed by two vertical incisions made on either side of the ankle. Firm union in a deformed position was found to have occurred. The union between the fragments was cut away with a chisel and considerable fibrous tissue removed. The fragments were then approximated with considerable difficulty and held in place by silver-wire sutures. The wounds were closed as usual and without drainage. The foot being held in its normal position, immobilization was secured with a plaster-of-paris dressing. Primary union had occurred and the skin sutures were removed on the tenth day. At the end of three weeks, union was fairly firm, there was no deformity, and the patient was discharged to the out-patient department, wearing a plaster dressing and using crutches.

CASE 20.—*Ununited Fracture of the Tibia.*—C. C., 31 years (B. C. H., Surgical Records, B., vol. 398, p. 78).—Admitted April 21, 1903, to the service of Dr. Cushing. The patient was injured by a wheel of an ice wagon passing over his left leg.

Physical Examination.—There is considerable swelling and ecchymosis of the left leg, and at the junction of the upper and middle thirds there is crepitus, abnormal mobility and deformity of the tibia, with some overriding of the fragments.

Reduction was apparently accomplished under anesthesia and the parts immobilized in a plaster-of-paris dressing. At the end of three months, no union had occurred and the operation was performed.

Operation.—Dr. Lund, Dr. Kelly. Ether anesthesia. An incision about five inches in length was made on the anterior surface of the leg at the seat of the fracture and was carried down to the bone. The upper end of the lower fragment of the tibia was found to be displaced backward and outward and separated from the upper fragment of the tibia by muscular and fibrous tissue. This was removed by a curette and scissors and the ends of the fragment freshened. Internal fixation was performed with heavy chromicized catgut, and the wound closed in the usual manner and without drainage.

Immobilization was secured with a plaster-of-paris dressing applied from the toes to the groin. The wound healed, primary union, and the skin sutures were removed on the eighth day.

Three months after the operation, the patient was discharged, using crutches. At this time union was firm, and, on account of the small portion of bone which was removed from the end of each fragment at the time of the operation, there was slight forward bowing at the seat of fracture.

CASE 21.—*Compound Fracture of the Humerus.* S. L., age 5 years (B. C. H., Surgical Records, B., vol. 402, p. 10).—Admitted June 17, 1903, to the service of Dr. Cushing. The patient was injured by being struck by a passing team.

Physical Examination. The left humerus presents a compound fracture about 1½ inches above the condyles, the skin wound being on the internal surface of the arm and about one inch in length. In addition, the patient has a closed fracture of the right femur about its middle.

Operation. Dr. Lund. Ether anesthesia. The left arm was prepared in the usual manner, and the wound, after being thoroughly irrigated with normal salt solution, was enlarged, exposing the seat of fracture. The fragments were approxi-

lated and held together by medium-sized chromicized catgut sutures. The wound was closed in the usual manner and with drainage. Immobilization was secured by means of a plaster-of-paris dressing, applied from the hand to the axilla, the elbow being placed at a right angle.

Following the operation there was considerable sloughing of the soft parts about the wound, leaving a portion of one fragment exposed and denuded of periosteum. At the end of ten weeks a sequestrum was removed and union had taken place at the seat of fracture. At the end of twelve weeks, the wound had entirely closed, and the patient was discharged to the out-patient department. Union was firm; there was very slight angular deformity, inward at the seat of fracture, and there was no motion at the elbow joint.

CASE 22.—*Compound Comminuted Fracture of the Femur.*—C. M., age 24 years (B. C. H., Surgical Records, B., vol. 402, p. 150).—Admitted July 4, 1903, to the service of Dr. Monks. The patient, while driving a fire engine, was injured by a train striking the wagon.

Physical Examination.—In addition to multiple contusions, there is a compound fracture of the left femur at the junction of the middle and lower thirds, the external wound being about four inches long on the external surface of the thigh at the seat of fracture.

Operation.—Dr. Lund. Ether anesthesia. The thigh was cleaned in the usual manner, and the wound, after being thoroughly irrigated with normal salt solution, was enlarged. Examination of the fracture showed considerable comminution of the fragments for a distance of three inches. The loose fragments were removed and the wound closed with interrupted silk-worm gut sutures, except at the lower angle, where several strips of iodoform gauze were introduced for drainage. The fragments were held in position externally by a plaster-of-paris spica dressing, extending from the toes to the waist. Following the operation, there was considerable sloughing of the edges of the wound, and during a period of three months small fragments of bone were removed from the wound. At this time there still persisted a small sinus, but firm union was present. There was three inches' shortening and no angular deformity. All apparatus was then removed. One month later the sinus was corrected and several pieces of necrotic bone removed. The patient was finally discharged six months after the time of injury, using crutches. This case was interesting on account of the large amount of bone which was lost (three inches), due to the comminution of the fragments, and was followed by good union and a fair functional result.

Figure 15 shows the poor anatomic result, which may at times follow fractures of the tibia and fibula when treated by non-operative methods. The loss of a laborer's earning capacity is apparent with such a result. This is a type of case which would have been followed by better results if subjected to operative intervention.

CONCLUSIONS.

In conclusion, it may be stated that all closed fractures do not require operative intervention for proper reduction and immobilization. In fact, perfect anatomic and functional results are obtained in the great majority of cases when treated by conservative means. There are, however, some cases in which reduction can not be accomplished under anesthesia, and in which the x-ray photograph shows faulty approximation of the fractured ends. There are other fractures in which we know from experience that union will occur only with deformity, and the functional results thereby lessened. Other classes of fractures are frequently followed by non-union. We should carefully discriminate between the various classes of fracture and select only those for this plan of treatment, which would not be followed by perfect anatomic and functional results, if treated by non-operative methods. The probability of infection following such operations in experienced hands and under proper surgical precautions, should be no more frequent than in operations on other structures.

Fig. 1.—Case 2. Closed fracture of the tibia and fibula. Skia-graph taken in an anteroposterior position before the operation. The degree of overriding is shown, and the tendency of the upper end of the lower fragment of the tibia to be displaced upward and outward.

Fig. 2.—Case 2. Closed fracture of the tibia and fibula. Skia-graph taken in a lateral position before the operation. The overriding and the backward displacement of the upper end of the lower fragment is well shown. In this case this sharp fragment was found piercing the muscles, and reduction would have been impossible by non-operative measures.

Fig. 3.—Case 2. Closed fracture of the tibia and fibula. Skia-graph taken in a lateral position six weeks after the operation. It shows well the third fragment which is so frequently present in

Fig. 4.—Case 2. Closed fracture of the tibia and fibula. Skia-graph taken in an anteroposterior view six weeks after the operation. It shows the extent of the resection and the preservation

Fig. 5.—Case 3. Closed fracture of the tibia and fibula. Skia-graph taken in a lateral position seven weeks after the operation. The characteristic displacement was present, as in Case 2. No resection of the fragments was necessary. The suture holes and the approximation show well.

Fig. 6.—Case 3. Closed fracture of the tibia and fibula. Skia-graph taken in an antero-posterior position seven weeks after the operation. The picture shows the retention of the fragments in the normal axis of the bone, also the suture holes.

Fig. 7.—Case 4. Ununited fracture of the femur. Skia-graph taken six weeks after the operation. The bone had been sutured with silver wire. The broken silver wire failed to retain the fractured ends in approximation. It shows well the disadvantage of silver wire as a suture material, as it is liable to break at any time when any angulation at the seat of fracture is produced.

Fig. 8.—Case 6. Closed fracture of the tibia. X-ray photograph taken in an antero-posterior position, before the operation. The spiral nature of the fracture is well marked. The displacement of the fragments is constant, the upper passing downward, forward, and inward; the lower, upward, backward and outward. The knowledge of the character of the displacement is of great value to the surgeon, in that it simplifies considerably the details and severity of the operation, and secures a perfect result.

Fig. 9.—Case 6. Closed fracture of the tibia. Skiagraph taken in an antero-posterior position four weeks after the operation. The approximation is not as good as it should be, but the length of time that had elapsed from the time of the injury to that of the operation necessitated some resection of the fragments.

Fig. 10.—Case 7. Ununited fracture of the radius. Skiagraph taken in a lateral position before the operation. The apparently good approximation, as shown in the photograph, was rendered inadequate, owing to the interposition of muscular tissue between the fractured ends.

Fig. 11. Case 7. Ununited fracture of the radius. Skiagraph

Fig. 12. Case 8. Ununited fracture of the radius. From a

Fig. 13. Case 8. represents the results obtained by the operation. The silver wire suture gives perfect approximation. The extent of regeneration from the periosteum is shown.

Fig. 14.—Case 11. Compound fracture of the humerus. Skia-graph taken in a lateral position five weeks after the operation. The preservation of the axis of the humerus is perfect. The excessive callus is probably due to the comminution of the fragments and absence of perfect approximation of the periosteum.

Illustration of the article by Dr. Mortimer Frank, showing fundus of eye in patient with amaurotic family idiocy.

Fig. 15. Malunion following fractures of the tibia and fibula. Skia-graph taken in an antero-posterior position of a fracture involving both bones of the leg. The union is very firm, but the loss of a laborer's earning capacity with such a result is evident.

A CASE OF AMAUROTIC FAMILY IDIOCY, WITH A SUMMARY OF REPORTED CASES.*

MORTIMER FRANK, M.D., B. S. (Mass. Inst. Tech.).
CHICAGO.

This uncommon disease is especially interesting to ophthalmologists because of the fundus changes which are pathognomonic and because Warren Tay, an English oculist, first drew attention to the subject in 1881. From that time until 1896, when Sachs proposed the name as now used, each observer described his case under a different title.

Amaurotic family idiocy is a fatal disease, commencing in the early months of infant life with muscular weakness progressing to almost complete paralysis, associated with a distinct symmetrical fundus appearance and terminating in death about the end of the second year. No definite exciting cause has been assigned. There is no evidence that inherited syphilis, consanguinity of parents or any of the usual diatheses is a factor. There is, however, a marked racial peculiarity. In all but six of the recorded cases the disease has occurred in Jewish children. Both male and female children are affected. There is a suggestive family predisposition in that more than one child in the same family is attacked, but with no regularity in the order in which this takes place.

The child is born at full term, sound and healthy, and continues so until about the third month. It then ceases to develop along normal lines and signs of muscular enfeeblement, especially of the back of the neck, are observed, with failure of sight. Should an ophthalmoscopic examination be made at this time, definite and characteristic changes in and about the macular region will be detected. Marasmus increases slowly, and the muscular enfeeblement becomes so pronounced that the child is unable to sit up and the head falls backward if unsupported. The grasp is feeble and objects placed in the hands are soon dropped. There is a decided cessation of mental development and the child becomes apathetic. Perception of light is present for a time, while hearing remains hyperacute, so much so that any sound causes the child to start.¹ The sense of taste is preserved, and interference with deglutition occasionally happens. Finally, paresis or paralysis, either flaccid or spastic, of the greater part of the body appears. The deep reflexes may be exaggerated or diminished and occasional spasmodic contraction occurs. The temperature is normal throughout the course of the disease. Falkenheim calls attention to an explosive laughter, which could be induced in the reported case by blowing on the child's face. Total blindness finally ensues from optic atrophy. The duration of life varies from one and a half to two and a half years.

The following case was referred to me by Dr. A. C. Cotton, through whose courtesy I am enabled to publish it. Minute details are omitted, as the history will be more fully gone into when published by him:

R. H., female, aged 1 year, was examined March 27, 1905. She is the youngest of four children, the remaining being boys in good health. There is a history of one miscarriage. All the children have been breast fed. The parents are of Jewish extraction, with no history of consanguinity or syphilis. The appearance and nutrition of the child was good and the head was well formed and of normal size. She was listless, unable to sit up and apathetic and understood nothing. The reflexes were exaggerated and especially noticeable was the abnormal susceptibility of the child to noises.

* Read before the Chicago Medical Society.

1. Kingdon observed the changes in the temporo-sphenoidal lobe much less marked than in other regions of the brain, which probably explains the fact that hearing is unaffected.

The following ocular symptoms were noticed: The pupils were about 1.5 mm. in diameter, equal in size and reacted slowly to light, but light thrown into the eyes failed to give any evidence of vision. A drop of atropin solution was put into each eye to facilitate the examination. The discs were atrophic, grayish in color, and the outlines well marked. The retinal vessels were of normal size. The fundus picture, as described elsewhere, was typical of the disease.

The ocular symptoms are pathognomonic of the disease and are present early. In the beginning there is no change in the appearance of the discs and the child is able to see. Later on there is definite optic atrophy and total amaurosis. Optic neuritis has been observed to precede optic atrophy. The changes at the macula are characteristic and unique and always symmetrical. These changes remain unaltered throughout the course of the disease. About the macula is a nebulous area, grayish-white in color, slightly raised above the surface of the retina and about two to three times the size of the optic disc, with softened edges gradually blending with the normal fundus. The patch is somewhat oval in shape with the major axis horizontal. In its center, coinciding with the fovea centralis, but larger, is a dark red or liver-colored spot clear cut in outline. Surrounding the central spot can be seen distinctly the tiny retinal vessels. Strabismus and nystagmus has been observed in some cases. There is no recorded regularity as to the condition of the pupils.

In but six cases have the eyes been studied microscopically. Treacher Collins reported the first findings in Kingdon's two cases. He found the retina much thickened at the yellow spot, due to enlargement of the outer molecular layer, the tissue of which showed a spacing-out which he regarded as indicative of edema. The most marked changes occurred in the neighborhood of the fovea and became less evident toward the periphery of the affected area. The retina was detached from the choroid, and had been thrown up in folds above the macular region, probably due to faulty fixation with Müller's fluid. The optic nerve was atrophied and showed an increase of interstitial connective tissue and a large number of round cells. At the time of this examination no study had been made of the ganglion cells.

In the third case, that of Peterson's, examined by Ward Holden, the results were unsatisfactory, owing to the advanced postmortem changes.

In the fourth case, that of Hirsch, also examined by Holden, he reported the essential changes in the eye to be degeneration of the ganglion cells of the retina, and of the nerve fibers of the optic nerve and tracts.

In the fifth case, that of Mohr, examined by Preisz, he reported edema and thickening of the outer molecular layers, especially the fiber layer of Henle, which composes the outer portion of this layer in the region of the macula. This edema is ascribed to a probable angioneurotic disturbance, the result of pathologic alterations in the cervical cord. No mention is made of the condition of the ganglionic cells. The outer segments of the rods and cones were degenerated and the formation of a granular substance found between the external limiting membrane and the choroid.

Holden was the first to show the relationship between the fundus changes, especially at the macula, to those found in the central nervous system. He likewise regards the atrophy of the optic nerve, both as an ascending and a descending degeneration, and dependent on a common cause and related to the changes in the cerebral nervous system, as both are embryologically related.

In the sixth case, that of McKee, examined by Shumway and Buchanan, the views of Holden were confirmed.

The nebulous area about the macula, it is reasonable to suppose, results from the swollen and degenerated ganglion cells present in larger numbers in the macular region rather than to an edema. Two facts speak against edema: first, the unchanging appearance of the lesion for months, and the absence of any veiling of the minutest vessels in this area (Falkenheim).

In the fovea the ganglion cells are absent, but at the margin of the fovea the ganglionic layer is six to ten cells deep, gradually growing less until at the periphery it is only a layer of single cells. Thus we have the red center void of cells, next the dense white corresponding to the deepest portion of the layer, fading away gradually as the cells become fewer. In the vertical meridian the ganglion cell layer thins out more rapidly than in the horizontal, explaining the oval area about the macula having its major axis horizontal.

Sachs,² in his last paper, lays great stress on the morbid process in this disease affecting primarily, or at least to a great extent, the larger ganglion cells of the entire gray matter of the brain and of the spinal cord. These confirmed the cellular findings previously described by Hirsch³ and recently by Spiller.⁴

The following is a summary of the statistics of all the cases reported up to July 1, 1905: Thirty-two authors report 54 cases, with histories completed, and 20 additional cases alluded to. Of these patients, 22 are males, 25 females, and in 7 no sex is reported. Twelve postmortems have been performed, and in 6 cases the eyes have been examined microscopically. Twenty-seven cases occurred in Jews, 6 in Gentiles, and in 21 cases no data is given. In 15 cases nystagmus was present. The youngest patient was four months old; the oldest three and three-fourths years. The statistics compiled from my table differ from those published by Spiller and Falkenheim, owing to the omission from the list of the same case published by different authors.

THE ELIMINATION OF THE NOSTRUM TRAFFIC.

AN EVIDENT DUTY OF AMERICAN PHYSICIANS.*

M. I. WILBERT, Ph.D.

Apothecary at the German Hospital,
PHILADELPHIA.

What is a nostrum?

Why should nostrums be eliminated?

Why should physicians be interested in their elimination?

As an answer to the last and certainly the most directly interesting of these three questions it may be pointed out that, apart from the duties and obligations imposed on physicians, by the traditional oath of Hippocrates, the practice of medicine, in every state, is hedged about and protected by laws that are designed to prevent the ignorant and the incompetent from imposing on the people of the commonwealth, and also, in a measure at least, are designed to protect regularly licensed members of the medical profession from imposition and unnecessary competition in the practice of their science or art.

The members of the medical profession, on the other hand, in thus seeking and accepting the protection secured to them under these several statutory enactments, are expected to guard and to protect the lives of the citizens of the state from infection and disease and, incidentally at least, to point out the dangers and, if possible, prevent the use, or at least the abuse, of anything that will in any way endanger the health or the well-being of the individual members of the community.

It is in this capacity, as guardians of the health and the well-being of the individual members of the community, that physicians are in duty bound to take cognizance of the present widespread inquiry into the status of nostrums and their possible deleterious effects on the health and even the lives of unwitting or indiscreet consumers.

WHAT IS A NOSTRUM?

As an answer to the question, What is a nostrum? we may safely accept the usual dictionary definition and include as nostrums, or at least as objectionable nostrums, all medicines "the ingredients of which are kept secret for the purpose of restricting the profits of sale to the inventor or proprietor." Personally, I believe that the word nostrum, in keeping with its evident derivation from the Latin word *noster*, might properly include all medicines or medicinal preparations in which any one individual or firm claims, or maintains, a proprietary right, either by secrecy, trade privileges or official letters patent, thus making the word nostrum practically synonymous with the term proprietary medicine, as used at the present time. I myself believe that this broader definition is quite in harmony with existing conditions and fully in keeping with the facts.

Restricting the word nostrum, however, as being applicable only to proprietary medicines which are in any way secret, or for which extravagant claims are made, as therapeutic agents, I am sure that you will readily agree with me that under no condition is the use of such substances in keeping with what purports to be a scientific occupation, and least of all can their use be made compatible with that most important and most responsible of all duties, the conservation and preservation of human lives.

Surely you will agree with me that if there is any one field of scientific investigation in this wide world that should be absolutely free from commercialism, or even a suspicion of secrecy, trickery and fraud, it should be the science of medicine in the very widest application of that term.

How far removed we are from even an approximate realization of this ideal becomes evident when we learn that, at the present time, nostrums appear to constitute fundamental necessities in the armamentarium of many physicians, as well as being the ever-ready cure-all recommended by blacksmiths and tailors.

The reasons for this unfortunate state of affairs are varied. In the first place we must not forget that nostrums, even the vilest of them, are not readily differentiated from what might be perfectly legitimate proprietary medicines, and we must also bring ourselves to realize that manufacturers of otherwise unobjectionable remedies have adopted, and are now using, highly objectionable methods in exploiting their preparations.

Another potent factor in developing the present widespread use of nostrums by physicians is to be found in the fact that the physician who is at all susceptible to extraneous influences can always find, ready at hand, literature suggestive of the curative qualities of nos-

trums. Even in some of our present-day monographs and text-books on therapeutics, in which the application and uses of the better known and official remedies are fairly buried in a mass of contraindications and verbose descriptions of untoward results, we find that the indications and uses of the newer remedies are frequently copied verbatim from the advertising material sent out by the manufacturer, who usually takes very good care that this kind of literature never contains even a suggestion of anything derogatory to the product he advertises.

The medical practitioner, not appreciating that the derogatory testimony, in connection with the older and official remedies, represents the accumulated evidence of decades, if not of centuries, of continued use, naturally enough turns to the remedy that has little or nothing recorded against it. After a physician has met with repeated failures in the use of any given substance, he may casually inquire into the reason for this almost utter lack of disparaging evidence, in connection with the newer remedies. If he looks far enough he will find that one reason, and a very important one, is to be found in the fact that few, if any, of us care to give publicity to our failures, no matter in what line or in what direction.

The second, and by far the more potent and more evident, reason, however, is to be found in the fact that practically all new remedies belong to this gigantic class of nostrums that threatens to stultify and to debase the practice of medicine by suppressing all information in any way derogatory to the commercial success of any particular preparation.

"ETHICAL" PREPARATIONS.

Some of you may have the feeling that there is a deep, wide something that naturally separates so-called "patent" medicines, or popular nostrums, from the "ethical" proprietaries that are advertised exclusively to physicians.

I want to assure you, and to assure you most positively, that, at the present time at least, this chimerical something exists only in the minds of well-paid detail men, and is the justification that is so anxiously sought for by editors of medical journals that depend largely on the advertising of nostrums for their existence.

That manufacturers themselves do not appreciate this distinction is to be noted by the fact that 21 per cent., or fully one-fifth, of the members of the Proprietary Association of America are firms that exploit strictly "ethical" preparations, while an additional number of the members are connected either directly or indirectly with the manufacture, or at least the sale, of ethical preparations in addition to making nostrums for popular use.

That jobbers or wholesalers do not recognize the distinction is evidenced by the fact that antijag, antikamnia, celerina, cerebrine, curalene, opticura, ovarine and ozonine, to the number of some twenty-five or thirty thousand, nestle cheerfully side by side, in strict alphabetic order, in the proprietary medicine catalogues that are periodically issued by these firms. As for the retail druggist, he has long since found it to be to his advantage to array these articles promiscuously on his shelves, or even in his shop window, labeled at cut-rate prices.

If you were to go into the shop of the corner druggist and, as a layman, ask him to sell you an ounce of hydrated chloral, as such, he would probably refuse. If, however, you were to ask him to sell you a bottle of bromidia, he will be only too glad to supply you with

practically the same amount of chloral, plus a number of other active ingredients, at cut-rates, that is, from 10 to 25 per cent. below the regular retail price. Some druggists might refuse to sell you half an ounce of acetanilid, but practically all will willingly sell full or broken packages of antikamnia, Kohler's antidote, ammonal, orangeine or a hundred and one similar compounds, including their own. Cut-rate druggists also advertise phenacetin, sulfonal, trional and even veronal, though they are prevented by a sense of decency or propriety, or it may be by law, from offering codein, morphin or cocain in their regularly issued price lists. Some retail druggists have gone even further in their zeal to popularize "ethical" proprietaries. They occasionally issue a special cut-rate price list of "Prominent Pharmaceutical Products Frequently Prescribed by Physicians." Such a little book is useful in two ways; it induces your patient to buy outright a full bottle of the nostrum that you have prescribed for him, at the same time retaining your prescription as authority for its continued use; and it also serves as an indication of the ethical preparations that are available to such of the laity who think that, because they are prescribed by doctors, "ethical" preparations are necessarily more efficient than the ordinary "patent" medicine or popular nostrum.

If the promiscuous sale of peruna, Hostetter's bitters and Pinkham's compound is to be discouraged and decried, on account of the alcohol they contain, if the sale of catarrh cures containing cocain is to be generally prohibited, what steps, if any, should be taken to discourage the promiscuous sale of such "ethical" preparations as bromidia, papin, chlorodyne, somnos and a host of other scarcely less dangerous nostrums, such as vin Mariani, that are daily sold to the laity?

ADVERTISING METHODS.

That even the most reputable manufacturers of proprietary preparations have developed a tendency to suppress the publishing of derogatory reports must be evident to all who will take sufficient interest to peruse the advertising material they send out. You have, no doubt, been appealed to by manufacturers of synthetic chemicals to report your successes with the use of their preparations. But have you ever been asked to report your failures, the untoward results that you have met with or the drug habits that have been formed? Have you ever met with an article outlining the contraindications for the use of their remedies in the pamphlets with which these firms supply you at frequent intervals? Do you believe that the active coal-tar preparations are applicable in all cases, regardless of age, sex, or physical infirmities? Do you believe that no dangerous and even serious accidents have ever followed their use, and do you know that practically all of the well-known preparations of this character are freely sold to and widely used by the public, regardless of possible consequences? If firms that are guaranteed an absolute monopoly of their products for a period of seventeen years and are further assured of a perpetual prestige by virtue of having been the first to bring forward any given remedy in this country, will deliberately and persistently discriminate in favor of propitious and at times even garbled reports, what can be expected of firms whose very existence depends on a more or less thinly veiled trade secret? Can you even conjecture the depths of direct or inferred dishonesty to which such concerns will descend to create a market for their products?

Properly to appreciate the reasons why the present-

day traffic in nostrums should be done away with we must fully realize that the harmful effects are invariably due to promiscuous and indiscriminate use of any one of them in all, or nearly all, cases that present themselves while that particular nostrum is in vogue. While physicians themselves are largely to be blamed in this direction, it is to the cunningly worded and frequently misleading advertising matter sent out by the manufacturers that we must look for the direct incentive to the misuse and abuse of nostrums. For illustration: When the manufacturers of one of the widely advertised mud poultices claim that their preparation will cure appendicitis, it is an untruth, and in the hands of the inexperienced and the unsophisticated this statement becomes a dangerous untruth and leads to the sacrifice of human lives. When the manufacturers, or rather the vendors, of that elegant confection that "works while you sleep" claim that their product will cure insomnia, liver troubles, intestinal disorders and a host of other more specifically mentioned ailments, they are telling an untruth and a dangerous untruth, because it leads the laity to temporize with what may be serious affections, or, even worse, because the very use of this nostrum may produce a condition that requires the regular use of cathartic medicines and thus lead up to an atonic condition of the intestinal tract, chronic constipation, a reduced power of resistance and a thousand and one possible complications that may follow in their wake.

These are but suggestions of the possibilities for harm that are to be found in connection with the twenty-five or thirty thousand nostrums exploited at the present time. Even admitting that nostrums are active and efficient and that they are useful under certain conditions, they are nevertheless dangerous and to be condemned, because they are not openly and honestly put out on their merits.

From patented synthetics to liqozone and peruna is, indeed, a far cry in the world of proprietary medicines, and what a mass of trickery, deceit, dishonesty and fraud is to be found between them!

THE COUNCIL ON PHARMACY AND CHEMISTRY.

Even to enumerate all of the preparations that are advertised or available would take hours, if not days. To sort them over and to estimate their probable worth, on the available evidence, is a task that would appear to be well nigh interminable. Some attempt is now being made to sort out from this fathomless, boundless mass of material those preparations that are generally considered to be worthy of recognition or that are at least evidently less objectionable than the rest.

This attempt is being made, in connection with the American Medical Association, by the recently instituted Council on Pharmacy and Chemistry. It is the object of this council to gather evidence for and against the several proprietary preparations that are now being offered to the medical profession of this country, and by comparing the evident status of the several remedies with the rules that have been adopted as a minimum of requirement to decide on their eligibility to appear in a semi-official list or book to be called "New and Non-official Remedies."

That this effort is not being made any too early must be evident to those who realize the ever-increasing number of evidently fraudulent nostrums that are being exploited at the present time. The difficult and thankless task of selecting the more worthy proprietary remedies that confronts the members of the Council on Pharmacy

and Chemistry of the American Medical Association would certainly appear to merit your attention and active co-operation.

CO-OPERATION OF THE PROFESSION.

I believe it is your duty, however, to do more, infinitely more, by taking a personal interest and an active part in this tremendously important undertaking of eliminating at least the more objectionable nostrums of all kinds from popular sale and certainly to banish from the practice of medicine the more objectionable compounds that are exploited as "ethical" preparations.

I also believe that it is the duty of each one of you individually to become thoroughly acquainted with at least some of the phases of the deceit and deception that are practiced by the promoters of proprietary medicines or nostrums and to insist that manufacturers of remedies, designed ostensibly for use by medical practitioners, exploit their wares honestly and in keeping with their merits.

I believe it to be your duty to inquire into the influences that manufacturers of nostrums, individually as well as collectively as members of the powerful and wealthy Proprietary Association of America, have exerted, do exert and will exert on the secular as well as on the professional journals of this country, and to try to overcome or, if possible, to nullify this influence by your concerted efforts and action.

It will be idle for you to suppose that any appreciable change in the existing conditions can be brought about by your say-so or by your wishes. The impending conflict, to eliminate only the more evident nostrums from the pale of respectability, while it is admittedly disagreeable and unpleasant, is full worthy of your aid and your attention. For ultimate success it will be essentially necessary that each one of you contribute, not alone occasionally but frequently and persistently. You can contribute most readily if you will insist that the untoward results from the use of proprietary medicines be given proper publicity in connection with the name of the remedy. You can also assist by informing your patients and your friends of the possible dangers that are to be encountered in the promiscuous or long-continued use of even the least objectionable and apparently most harmless nostrum.

You can also contribute if you yourself will desist from the use of proprietary medicines, with the composition or the limitations of which you are not thoroughly familiar. You will be able to do this the more readily if you will but become more thoroughly familiar with the almost inexhaustible fund of well-known and well-tried remedies of the Pharmacopeia, remedies that are easily tested, readily proved, widely used and are certainly obtainable in any section of this country.

This I believe to be your duty, as citizens of the commonwealth, in return for the protection and the privileges that are being accorded to you.

I believe it to be your duty to your patients, as physicians, in order to merit their continued confidence and patronage. And, last, but by no means least, I believe it to be your duty to yourselves, as men, in order to foster and to preserve your own self-esteem and self-respect.

Treatment of Pelvic Diseases.—Dr. J. F. W. Whitbeck says that in the treatment of pelvic diseases a knowledge of general internal medicine and of the general principles of surgery is of the first importance to the patient, and must be of the highest advantage to the physician himself.

THE TREATMENT OF LEUCORRHEA WITH THE ACTUAL CAUTERY.*

GUY L. HUNNER, M.D.

Associate in Gynecology, Johns Hopkins University.
BALTIMORE.

There are probably few members of this society who are specialists to the extent that they do not treat diseases peculiar to women. If I were to ask what symptom is complained of most frequently in your experience with such diseases, I believe the majority of you would agree in one answer. Certain it is that during several years' experience in a large clinic the question most frequently asked me by visiting physicians was, "What do you do for leucorrhœa?" Rather the question was usually presented in this form, "How do you treat endometritis?" the general belief among physicians being that leucorrhœa is an expression of chronic inflammation of the endometrium. Our laboratory experience demonstrates, however, that chronic inflammation of the endometrium is comparatively rare, while cervical inflammation is one of the most common of lesions.

The physician's first duty in treating a patient complaining of leucorrhœa is to locate, if possible, its point of origin. In some cases, particularly those of acute gonorrhœal origin, the inflammation may be confined to the vulvar region; but in the majority of the cases of longer standing the major portion of the leucorrhœal discharge comes from the cervix. If the patient complains of severe pain, with periodic discharge of pus and coincident relief of pain, one must carefully examine the glands of the vulva and urethra for evidence of abscess formation. The same periodic symptoms may arise from a tubal or tubo-ovarian abscess which is discharging periodically through the uterus or through a fistula in the rectum or vagina. It may be difficult, from the history alone, to distinguish between these two regions, but there should be but little difficulty in locating the seat of the abscess by a visual and bimanual examination.

Other sources of leucorrhœal discharge to be carefully borne in mind and excluded before beginning treatment are carcinoma and other ulcerative diseases of the vagina, cervix or fundus uteri, or a necrosing myoma of the fundus, or pelvic abscess from any origin discharging into the genital tract.

It is not my intention to enter into a detailed account of the present methods of treating leucorrhœa. I dare say that most of you have had more or less experience with douches, tampons, vaginal suppositories and various surgical methods, and I am confident that you have had very indifferent success with most of your cases. With douches your patient has kept fairly clean during the period that she has been faithful in their use. With tampons you have had apparent complete success, and your patient has reported herself cured only to return for treatment after a period of weeks or perhaps months. Operative measures may have given better results. Deep and thorough curettage of the cervix may have given permanent results in a few mild cases. The Emmet resection of the cervix has given partial success, while with a complete amputation of the cervix your patient may have been entirely relieved of her leucorrhœa.

The method that I wish to present for your consideration to-day will appeal to you because of its simplicity, and, in the event of its use, because of its results. I do not claim originality for this procedure, as it deviates only slightly from methods which we have used for a number of years.

During my early association with Dr. Kelly we often treated cases of cervical gland hyperplasia by making multiple radial incisions within the external os by means of a scalpel. This opened many of the dilated cervical glands, or Nabothian follicles, and allowed their mucous contents to gush out. I often noticed, however, that after recovery of such patients from their principal operation the cervical condition did not seem to be altered. Later it was our custom to take the hot blade of a Paquelin cautery and run it about over the hypertrophied mucosa of the cervix. This destroyed the superficial layers of tissue, causing a temporary necrosis. But as soon as the surface epithelium was replaced the leucorrhœa seemed to be as profuse as ever. My method grew out of these two, and consists in radial incisions deep into the cervical tissues by means of the cautery blade. I believe the other two methods failed because the incisions with the knife-blade simply emptied, and failed to destroy, the dilated cervical glands, while the surface application of the cautery failed to either empty or destroy the deeper glands. The deep radial cuts with the cautery empty the deep cervical glands and cause such a wide necrosis of tissue that many of these deep glands are obliterated in the healing process.

One great advantage of this method is that it may be applied in office practice without giving anesthesia of any kind. With the patient in the dorsal or lithotomy position, a broad-bladed Sim's speculum is introduced into the vagina, the anterior lip of the cervix is firmly grasped with a tenaculum forceps and the cervix is pulled down as near the vulvar orifice as possible. The nurse or assistant stands by with the cautery already heated. On transferring the cautery to the operator the nurse continues to work the cautery bulb with one hand, while she retracts the Sim's speculum with the other. The operator retains the tenaculum in one hand and manages the cautery with the other. The strokes should be made one at a time, the cautery being removed from the vagina after each stroke, as the patient feels the radiated heat on the vaginal walls. The patient is warned that she will feel the heat, but that she must not move, as there will be no actual pain. An exception to this rule is found in those patients who are suffering from a painful cervical scar. This condition is rare, and when present I use preliminary anesthesia by applying for ten minutes a cotton tampon soaked with a 20 per cent. cocaine solution. I have been able to relieve two cases of painful scar by this method.

The number and depth of the radial strokes depend largely on the condition of the cervix, but in general I make five or six strokes at each treatment, and burn to a depth of 2 to 3 mm., or, roughly, from one-eighth to three-sixteenths of an inch. The length of the stroke naturally varies with the conditions present, but it should extend over the area of the hypertrophied cervical mucosa, which generally covers all of the mucosa in sight. The treatments are given once in three weeks. A sterile strip of gauze is left in the vagina to take care of possible hemorrhage. The patient is instructed to withdraw this the next evening, and she is warned that the leucorrhœal discharge during the first week or ten days will be more profuse than ever, and that she may have some slight bleeding. She is instructed to go to bed and remain there if the bleeding is at all profuse. I have not known hemorrhage to take place the day of treatment, but there is often a little hemorrhage after three or four days, when the necrosis of tissue is at its height, and in one or two instances this hemorrhage has been sharp enough to alarm the patient. A daily douche is

* Read before the Cumberland Valley Medical Association.

recommended during the interval between treatments. I have had three treatments produce such a beneficial effect in a marked case of leucorrhea that the patient considered herself cured and did not come for further treatment. The usual number of treatments ranges from three to six and the greatest number of treatments I have given any patient is ten. I operated on this patient in August, 1903, during an acute attack of gonorrhea peritonitis, and did a supra-vaginal amputation of myomatous uterus, associated with gonorrheal pus tubes. After recovery from the operation she continued to have a profuse leucorrheal discharge from a lacerated and hypertrophied cervix. After ten cautery treatments the cervical mucosa is devoid of any evidence of inflammation and there is no leucorrheal discharge.

I have found the chronic gonorrheal cases the most obstinate ones to treat, it being necessary to destroy all of the deep cervical glands before the leucorrhea ceases. Another important consideration in these gonorrheal cases is that you may be able to greatly reduce the leucorrhea without stopping it entirely. In other words, the cervical catarrh may cease under the cautery treatment, but the leucorrhea may continue more or less profuse because of the endometritis and the metritis which are occasional sequelæ in an ascending gonorrheal infection. But many gonorrheal infections do not gain a foothold higher than the cervix, and some which do go higher are taken care of by nature and leave no permanent lesions beyond the cervix. These cases may be classed as curable by the cautery method.

The quickest and most brilliant results are obtained in the cases of cervical hypertrophy and eversion of the mucosa due to multiple child-birth.

I am sure you are ready to question me regarding the after-results of this mode of treatment, particularly with reference to child-birth. So far as I know, but two of my patients have borne children after this treatment, and both of these had perfectly normal labors. The first of these two women was the first case that I treated by this method, and, I think, represents the most brilliant result that I have obtained. She was a young woman with a child six years old by her first husband. She had been married to her second husband two years and was most desirous of having children. This aspiration, however, seemed beyond the range of probability because of a most profuse leucorrheal discharge. In spite of douches and tampons, this discharge was so profuse that in drying about the vaginal walls it formed thick membranes, and the husband, a physician, frequently brought casts of this membrane-like formation for microscopic examination, in hopes that it might throw some light on the nature of her disease. On her first admission to the hospital Dr. Kelly thoroughly dilated and curetted the uterus and performed an operation for relaxed vaginal outlet. On a third admission, nine months later, a vaginal celiotomy was done, and the left Fallopian tube was removed because of inflammation. At this operation Dr. Kelly made a thorough application of the Paquelin cautery to the hypertrophied cervical mucosa. During her convalescence the profuse leucorrheal discharge persisted, and it was in her case that I began the method of deep radial incisions with the cautery. She left the hospital after my first treatment, and I have no record of the number of treatments I gave after her dismissal from the hospital, but I am sure that it was not more than three. After their arrival at their distant home I received frequent letters expressing deep gratitude for her delivery from the disagreeable leucorrhea, and one year after her return she had a normal labor.

While the necrosis and obliteration of the deep cervical glands must result in a scar tissue formation, I believe that with my method of radial incisions enough healthy stroma persists to prevent anything like an universal circular scar, such as we get by complete amputation of the cervix, and for this reason we need not fear dystocia at labor.

In conclusion I would again impress on you the necessity for first making an accurate diagnosis before beginning to treat any case of leucorrhea. If you find an eroded cervix and have the least suspicion of beginning cancer, be sure to place some of the suspicious tissue in the hands of a competent pathologist before wasting time in any form of treatment. If you are dealing with a fresh case of gonorrheal infection, do not use the cautery or any other form of tissue-destroying treatment that might stir up a cervical infection and carry it to higher localities. In acute gonorrhea I use first the douches and later the tampons, and if the leucorrhea persists after twelve weeks and is seen to come from the cervical glands I begin the cautery treatment. In the chronic gonorrheal cases, do not persist too long in the treatment of the cervix, for the leucorrheal discharge may depend on inflammatory conditions higher in the uterus.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN. CHAPTER IV.

THE ACETANILID GROUP.

The enormous growth of the traffic in proprietary remedies mainly composed of acetanilid and allied substances is probably the most potent factor in arousing physicians to a realization of the part they play—often unconsciously—in furthering the selfish schemes of unprincipled manufacturers. The Council on Pharmacy and Chemistry of the American Medical Association has shown that antikamnia, phenalgin, salacetiin and ammonol are mere mixtures of acetanilid with other substances, and we can no longer prescribe these acetanilid mixtures under the impression that we are using true chemical compounds. It is probable that acetanilid figures more extensively in self-drugging than does any other single substance.

Official Antipyretics.

The following are official:

ACETANILIDUM.—U. S., Br., Ger.—Acetanilid, Antifebrin, Phenylacetamid, the monoacetyl derivative of anilin, occurs in colorless crystalline laminae or powder, permanent in air, odorless, of a slightly burning taste, and very slightly soluble in water.

It was first prepared by Gerhard in 1852, but was not used medicinally until nearly thirty years later, when it was introduced under the trade-marked name of Antifebrin. It is now employed very extensively, its extreme cheapness—less than 2 cents an ounce—causing it to be used as the basis of many pretended synthetics.

Average dose: 0.20 gm. (3 grains).

PULVIS ACETANILIDI COMPOSITUS.—U. S.—This has been made official to serve as a substitute of uniform standard for the host of more or less similar compounds, such as we have enumerated above, which have come into such unfortunate vogue.

The official preparation consists of 70 per cent. of acetanilid, 10 per cent. of caffeine and 20 per cent. of sodium bicarbonate.

Average dose: 0.3 gm. (5 grains).¹

ACETPHENETIDINUM.—U. S.—Acetphenetidin, better known as Phenacetin, is official in British, German and other European countries as Phenacetin. It is officially described as Acetpara-phenetidin, a phenol derivative, the product of the acetylation of para-amido-phenetol. Phenacetin occurs as white glistening scales or a fine crystalline powder, odorless and nearly tasteless. It is soluble in 925 parts of water and in 12 parts of alcohol. Phenacetin was patented in this country in 1889, though it is claimed to have been used in Germany at least two years previously. The patent expires next March.

ANTIPIRINUM.—U. S.—Antipyrin is official in France as Analgesin, in Great Britain as Phenazonum, and in Germany as Pyrazolonum—phenyldimethyleum. Chemically, it is described as Phenyl-dimethyl-pyrazolon, and is obtained by the condensation of phenyl-hydrazin with aceto-acetic acid and subsequent methylation of the product. Antipyrin occurs as a colorless, almost odorless, bitter tasting, crystalline powder, that is readily soluble in water and soluble in about 1 part of alcohol.

Average dose: 0.250 gm. (4 grains).

Antipyrin was first prepared by Dr. L. Knorr of Erlangen, in 1884; it was investigated physiologically by Professor Fiehehn, who reported it as an active antipyretic.

It will be more satisfactory to consider the therapeutics of these antipyretics collectively, with occasional comments on the separate members of the group.

They are mostly used for headache and for the reduction of temperature in fevers of an intermittent type, but it must not be forgotten that they do not remove the underlying cause, and that the use of these drugs in continued fevers is liable to be harmful, since the temperature is sure to return to its former height, or to go even higher, when the action of the antipyretic has worn off.

The alarming collapse that may follow even a moderate dose of acetanilid serves as a warning against its use when there is reason to suspect any tendency to that condition. On the other hand, a sudden lowering of the temperature in fever may result in collapse symptoms wholly independently of the nature of the remedy employed. Acetanilid has the greatest and phenacetin the least tendency to produce collapse among the official preparations of this nature. It is to overcome this tendency that caffeine is used in the official compound acetanilid powder, but it is doubtful if it is of any great value in guarding against this collapse. There can be little doubt that many of the sudden deaths, of which we so constantly read, occurring without apparent cause on the streets and elsewhere, are in reality due to overdosing with nostrums containing acetanilid.

Women particularly should be cautioned against the promiscuous use of nostrums of this type during menstruation.

When it is remembered that antipyrin and acetanilid are derived from phenylhydrazin, and anilin—active blood poisons—it is not surprising that the official derivatives possess the properties of these drugs in a minor degree.

A peculiar cyanosis is often seen about the ears, the lips and the nails, particularly after large doses of acetanilid, due to its action on the red blood cells; this has been noticed even in the absence of hemoglobin in the blood.

Acetanilid in large doses causes destruction of red blood cells, and methemoglobin may be thrown into the plasma.

The collapse seen after ingestion of the antipyretics, particularly acetanilid (least with phenacetin) is due to several causes. Probably the most frequent cause is the mere lowering of the temperature which exposes the collapse actually existing but hidden by the high temperature. This result is not to be charged to the antipyretic. It is treated exactly as

collapse from any other cause would be—by stimulation. Very large doses of the antipyretics act on the heart muscle, causing depression, and on the vasomotor center, causing collapse.

The acetanilid habit is not rare and it leads to a deplorable condition, but the symptoms generally disappear when the drug is withdrawn.

Profuse perspiration is a disagreeable effect, more frequently seen after acetanilid and antipyrin than after phenacetin. If this is so annoying as to demand interference, a hypodermic injection of 0.5 mg. (1/150 grain) of atropin will be found effective. Redness and irritation of the skin are frequently seen after the use of the various antipyretics of this group. They are probably due to vasomotor changes.

Antipyrin in solution has been used extensively to check the bleeding of superficial wounds, and all the various members of this group are to some extent antiseptic.

While so much space has been devoted to the contraindications and untoward effects of these agents, it is not with a view of discouraging their use, but rather that the physician may avoid the disappointments which arise from their use in unfavorable conditions.

Acetanilid may be given alone in powder or in capsules, in adjuvant or aromatic elixir, or suspended in syrup or mucilage of acacia. The compound acetanilid powder affords a convenient form for the relief of headache. A dose of 0.3 gm. (5 grains) in powder or capsule is usually effective; this may be repeated once an hour if necessary, but the more frequent repetition is to be avoided.

Compressed tablets of such insoluble substances as phenacetin and acetanilid are not recommended as they disintegrate slowly.

An acetanilid powder, containing ammonium carbonate instead of caffeine, is used in the German Hospital of Philadelphia,² when it is desired to avoid the cerebral stimulation of caffeine.

Antipyrin is very soluble in water and in alcohol, and hence it may be given in simple aqueous solution, in aromatic elixir or in powdered form.

Acetphenetidinum (phenacetin), being less objectionable than acetanilid and antipyrin, may be expected to replace them very largely when its price is reduced. Its insolubility in water has led to its extensive use in powder and in capsules.

A combination of phenacetin, caffeine and sodium bromid has attained considerable popularity; these may be combined in various ways.³

Chemistry of These Preparations.

A brief review of the chemistry of the antipyretic group will show the relationship of the various members to each other.

Quinin being a derivative of quinolin, many attempts were made to produce it synthetically, with the resulting discovery of a number of quinolin derivatives which possess antipyretic properties, but all of them dangerous because of their tendency

2. R. Acetanilid	grs. xxii	1
Sodi bicarb. of each	grs. xl	5
Ammon. carb.	grs. xl	75
This is sufficient for ten powders of about 0.3 gm. (5 grains) each, one being given every three or four hours to reduce fever. For headache one is given and repeated if necessary in an hour.			
3. R. Acetphenetidin (phenacetin)	grs. xv	1
Caffein	grs. viii	5
Sodi bromid	31
Elixir adjuvant	31
			30

The mixture is to be shaken and two teaspoonfuls given as a dose. This is often used for headache, one dose being usually sufficient.

Sill another, widely used, acetanilid mixture is a migraine elixir that is being exploited by a number of manufacturers. A representative formula, for a preparation of this kind, may be given as follows:

R. Acetanilid	grs. xxx	2
Caffine	grs. iii	2
Sodi bromid	31
Alcohol	31
Elixir aromatic, q. s. f.	31
			100

Average dose 5 c.c., or 1 teaspoonful.

If 20 c.c. of tincture of cardamon be added to this, or if adjuvant elixir (which is also official), be used instead of the aromatic, the appearance of the mixture will be much enhanced and the psychological effect increased.

1. It should be noticed that the dose of acetanilid in the mixture is larger than the official dose of acetanilid; yet it is supposed to act more effectively when mixed with sodium bicarbonate. It is to be regretted that such a combination has been given official recognition. The reason, of course, is evident—persistent advertising of certain nostrums has created an abnormal demand for acetanilid combined with a supposed heart stimulant. But, as it is extremely improbable whether caffeine does counteract the harmful effects of acetanilid, it is not wise to recognize such a combination even to meet a supposed demand.

to produce collapse. All of these are now practically obsolete.

Another substance having antipyretic and collapse actions is phenylhydrazin, which is of interest because of its derivative, antipyrin. Hydrazin NH_2 (or H_2N-NH_2), which is formed by the union of hydroxylamin and ammonia, usually exists in combination with an organic radical. Starting with the benzene ring, C_6H_5 , or

phenol (carbolic acid) is formed by replacing an H with OH. If this OH in turn be displaced by the hydrazin radical, phenyl hydrazin is formed thus:

phenol + hydrazin = phenyl hydrazin + water.

Though many derivatives of phenyl-hydrazin have been exploited, antipyrin and its compounds are the only ones in general use.

When the practitioner uses drugs which at best are so potent for harm he will do well to employ them in their simplest form rather than in such unofficial combinations as hypnal (chloral and antipyrin) or salpyrin (salicylic acid and antipyrin).

Acetanilid or phenyl-acet-anilid is obtained by the action of boiling glacial acetic acid on anilin or phenyl-amid, as it may be termed. By introducing "acet" before "amid" the chemist name is derived.

When other acid radicals replace that of acetic acid similar compounds are formed, which are in no wise superior to the official. Thus we have benz-anilid and exalgin (or methyl acetanilid), the latter differing from acetanilid only in having a CH_3 group replacing an H.

It will be understood from its chemistry why acetanilid can be prepared so cheaply and, therefore, why it is so extensively employed in the nostrum traffic.

Phenetidin is important as the basis of the phenacetin group. Chemically it is the ethyl ether (sulphuric, so called) of amido-phenol. If an amid group (NH_2) replaces the H in the para position (opposite to the OH) of phenol

we have para-amido-phenol, and if the OH is then replaced by ether we have phenetidol. Various acid radicals may replace an H of the NH_2 . If it be the acetic acid radical we have phenacetin, if lactic acid we have lactophenin.

These formulas may appear complex, but a careful examination of them will show the relationship existing between the various members of the group. If a practitioner finds the official phenacetin unsuited to his purpose in a given case, it is not probable that another compound, differing merely in the nature of an acid radical, will prove more beneficial.

Among the phenetidol series there are, besides the official phenacetin, many in which the syllable "phen" indicates the phenetidol source. They include phenocoll, salophen, lactophenin and many others.

We shall have occasion to mention urethane (ethyl carbamate) among the chloral hydrate group, and it may be said

that several of its derivatives have been used as antipyretics, but they do not merit further consideration here.

In connection with the subject of antipyretics we may mention a number of substances which, except historically, are now of little interest. Kairin, discovered by Dr. O. Fisher in 1882, was the first of the coal tar compounds to be introduced as an antipyretic on the strength of physiologic experiments. It was also one of the first of the medicinal synthetic chemicals to be patented. The older physicians may remember its widespread use and some of the exaggerated claims that were made for it and how, despite this, it fell into disfavor and was soon forgotten.

Thallin, made by Dr. Skraup in 1884 and investigated in the clinic of Nothnagel, soon shared the fate of kairin, despite liberal advertising.

RESORCINOL.—U. S.—Resorcin (U. S. P. 1890) discovered by Hlasiwicz and Borth about 1862, was used as an antiseptic and later as an antipyretic, but was found to be too dangerous for the latter purpose. It may be absorbed even after external application, when its effects resemble those of phenol (carbolic acid).

The official salicylic acid, discovered in 1839, was introduced as an antiseptic in 1873 and later as an antipyretic. The salicylates now find their greatest usefulness in the treatment of acute rheumatism. They will be discussed later.

THE CHLORAL HYDRATE GROUP.

The chloral hydrate group includes, besides Chloral Hydrate, Chloroformamid (Chloralamid), Paraldehyd, Ethyl Carbamate (Urethane), Sulphonmethane (Sulphonal and Sulphonethylmethane (Trional). Several of these preparations are so well known that we may dismiss them with a few words, but some of them may be profitably discussed at greater length.

It is easy to drug anyone into unconsciousness, but the members of this group do not possess curative properties and at most they only secure rest and sleep for the patient. Chloral hydrate is dangerous and we wish to point out some of the dangers attending its use, either alone or in the nostrums which contain it.⁴

All authorities agree that it is unjustifiable to use large doses of chloral hydrate, either alone or in combination with other official drugs. When a moderate dose of chloral hydrate fails to induce sleep in cases of severe pain, it is very much more rational to give a dose of morphin, or other analgesic, than to repeat the chloral hydrate indefinitely. The chloral hydrate habit is not rare, and if its sale at cut rates in the shape of nostrums with fanciful names is to go on unchecked, we can hardly hope to see any diminution of the baneful practice. When we employ hydratid chloral and sodium, or potassium bromid in simple solution it is with full cognizance of the danger, but because the exigencies of the case demand their use, and we only use them with caution.⁵ In a general way the contraindications for chloral hydrate are the same as for chloroform. In the present edition of the Pharmacopeia it is official as:

CHLORAL HYDRATUM.—U. S.—Hydrated Chloral.

Average dose: 1 gm. (15 grains).

Of the unofficial, more or less closely related drugs, hypnal (antipyrin and chloral hydrate) has been mentioned. Dormiol

4. In Chapter II attention was called to Bromidia, which is directed to be given in as much as teaspoonful doses every hour until sleep is produced, pain being mentioned as one of the indications for its use. Since chloral hydrate is not an anesthetic, except in unsafe doses, it is readily seen how dangerous this advice is, particularly when we are dealing with such intense pain as that encountered in appendicitis, even admitting that the preparation contains the other ingredients claimed.

5. A fairly safe and very efficient hypnotic commonly used in Bellevue Hospital in New York affords a convenient form of using sodium bromid with hydrated chloral.

R. Chloral	℥ss.	xx	1/20
Sodii bromidi	℥ss.	lxxx	5/20
Ser. aurantii cort.	3iv		16
Aque q. s. ad	3i		30

M. Two teaspoonfuls are given at a dose, and this may be twice repeated at intervals of an hour if necessary, but more than two doses are rarely required in the absence of severe pain.

The hydrated chloral may be slightly increased in the prescription in which case the dose should not be repeated more than once.

is a combination of amylene hydrate and chloral hydrate, while chloralose, a combination of chloral hydrate and glucose, partakes of the action of morphin and is rather expensive. Chloretone, a more recent product, is not entirely devoid of danger and is not always so certain in its action as chloral hydrate, while butyl chloral hydrate, or croton chloral hydrate, is one of the older compounds that has been found wanting and is now little used. Of the official compounds of this group we have:

Chloralamid and Paraldehyd.

CHLORALFORMAMIDUM.—U. S.—Chloralformamid. Chloralamid. This has practically the same action as therapeutic doses of chloral hydrate, the latter being formed in the body by decomposition of chloralformamid.

Average dose: 1 gm. (15 grains).

PARALDEHYDUM.—U. S.—Paraldehyd is slower in its action transparent liquid, slower in its action than chloral hydrate, but also safer. It has the disadvantage of a persistently disagreeable taste and odor. It is locally irritant and should not be used in irritable conditions of the stomach. It may be prescribed dissolved in 10 parts of water or in aromatic elixir, and is best administered cold, or followed by a cold drink.

Average dose: 2 c.c. (30 minims).

Sulphonal and Trional.

SULPHONMETHANUM.—U. S.—Sulphonmethane, Sulphonal, Diethylsulphonedimethylmethane, and

SULPHONETHYLMETHANUM.—U. S.—Sulphonethylmethane, Trional, Disulphonemethylethylmethane, may be considered together as they differ chemically only in the addition of an ethyl group in the latter.

Average dose of either: 1 gm. (15 grains).

Therapeutic Action.

The therapeutic action of these two preparations is practically identical, and the closely related tetronal might also be included in this statement. Trional is somewhat more soluble than sulphonal. While these substances are safer than hydrated chloral they are not wholly free from danger, as fatal cases of poisoning have been reported and the sulphonal or trional habit, while of more recent origin, bids fair to equal if not to excel the chloral habit in the number of its victims. These agents are usually given in powder, and owing to their slow absorption, should be given about two hours before they are expected to act. To insure more speedy action they may be given in solution, for which purpose they are dissolved, or at least suspended, in a cup of hot milk.

Urethane.

ETHYLIS CARRAMAS.—U. S.—Ethyl Carbamate, Urethane. This is a new official preparation which is claimed to be much safer than chloral hydrate, to which it would be distinctly superior but for the fact that its action is not so certain and because tolerance is soon acquired. It is best given in water, in which it is very soluble. The average dose is 1 gm. (15 grains).

THE BROMID GROUP.

The bromid group is so well known that it requires little therapeutic consideration here, but it is of considerable historic, as well as of practical interest. Potassium bromid was introduced by Balard about 1826, who supposed it to have properties analogous to those of potassium iodid. It was not until some time after 1850 that the present, sedative, uses of the bromids were accidentally discovered. During the past four decades the several alkaline bromids have received considerable attention and several of them are now official in every pharmacopoeia. In our own Pharmacopoeia, in addition to monobromated camphor, hydrobromic acid and the hydrobromids of a number of alkaloids, we have ammonium, potassium, lithium, calcium, sodium and strontium bromids official.

The average dose of any one of these alkaline bromids is 1 gm. (15 grains).

The abuses that have arisen in connection with substances belonging to this group are largely due to the misrepresentations that are made in connection with the efficiency or the character of the preparations containing them.

Strontium salts, particularly the bromid, were brought forward some years since, at exorbitant prices, as being infinitely

superior to the corresponding compounds of other elements. Experience has shown that, in the main, these claims were unfounded, though many, even now, claim that strontium bromid disturbs the stomach less than the corresponding sodium or potassium salt. Another claim that is frequently made by manufacturers of nostrums, like "Peacock's Bromides," is that they use "chemically pure" salts. Exactly what is meant by this claim is difficult to say, but the Pharmacopoeia gives us a number of readily applied tests by which the salts themselves may be tested. The manufacturers of nostrums, on the other hand, not infrequently add the very substances that are considered contaminations.

(To be continued.)

New Instrument

A NEW NEEDLE HOLDER.

JOHN EGERTON CANNADAY, M.D.
Surgeon in Charge Sheltering Arms Hospital
PAINT CREEK, W. VA.

I have for some time felt the necessity for a needle holder which would give easy access to the deeper and less accessible cavities of the body, for example, the pelvis, the cardiac portion of the stomach in certain gall bladder and other cases, more especially in subjects having much adipose and muscular tissue. At the same time I desired a strong needle holder for purposes of general utility and one in which the closed hand on the handle would not in any way obscure the operator's field of vision.

The usual holder often fails to secure the needle firmly when tissues of any degree of resistance are encountered. More particularly does this obtain should the needle be a trifle dull. Several types of holder break the needle if too firmly closed.

Bearing the above in mind, I have had a pistol grip or angular needle holder made which consists of four parts, an upper jaw branch, a lower jaw branch, which is continuous with the upper handle; a separate lower handle, which is connected with upper jaw branch by a lock, and a spring with ratchet catch. The upper jaw slides on the lower one by means of a runner dovetailed into a slot in the lower jaw. The parts holding the needle are finely serrated.

The dimensions of the instrument are as follows: From back at angle of holder to jaw, $4\frac{1}{2}$ inches; from back to bottom of handle, $4\frac{1}{4}$ inches.

This I find to be a suitable length for work in most of the deep cavities of the body. Surgically speaking, a shorter holder would be better suited for work on exterior parts of the body.

The holder can easily be taken apart or assembled. By bringing the lower handle forward it is unlocked, and the upper jaw can then be drawn out of the slot.

The advantages are: It renders areas comparatively difficult to reach more accessible; the hand is kept out of the line of vision; the needle is held firmly without breaking it; any kind of surgical needle is held perfectly, be it long, short, curved, straight, round, Hagelorn, flat, large or small. While it is easily taken apart for cleaning and is readily assembled, this instrument will not fall apart if handled with the ratchet open, as do some others. The arrangement of fulcrum, weight and power is such that a firm grasp on the needle is obtained by comparatively slight muscular exertion on part of the hand.

CHEMISTRY OF OSTEOMALACIA.

There is probably no class of diseases that is so little understood, and for which it is so difficult to obtain any conception of the etiology, as certain bone diseases. In the bone diseases in which the etiology is known, as in those of an infectious character, the processes going on are not at all understood. This is true in part because so little is known of the chemistry of bone metabolism. Of all the various chemical processes in the body, that which gives rise to bone formation appears to be the simplest because of the inorganic constituents involved whose chemistry is so thoroughly known. While the resulting products are known, however, as is true in many other tissue reactions, the manner in which these substances are brought there and the processes occurring before the final products appear are mostly in the realm of speculation. Bone absorption also is a process of the real nature of which we have little conception. We can not hope, therefore, to have a very clear understanding of diseases in which either the formation or absorption of bone is involved until much more is known about the process of normal calcification. Diseases of this kind should be studied carefully from the chemical point of view, for not only is it possible to obtain facts of importance in determining the nature of the disease, but it is also possible that such pathologic data may be of much importance in elucidating obscure points in normal physiologic processes.

It is with interest, therefore, that we note the recent contributions to the chemical study bearing on such problems as those referred to above. Wells recently reported before the Chicago Pathological Society the results of his studies on the chemistry of calcification. Using calcified material from tuberculosis and from other sources, he found a close correspondence between the proportion of inorganic constituents here and in normal bone. While not definitely demonstrating it, his results indicate that in these processes the fatty acids do not play an important part by combining with the calcium to form soaps. His experimental studies with animals showed the important fact that cartilage has the peculiar property of taking up the inorganic constituents much more rapidly than other tissues. The explanation of this probably depends on certain physical phenomena (absorption). Facts of this kind, of course, have a direct and important bearing on both normal calcifying processes and pathologic conditions.

A chemical study of the metabolism of the obscure bone disease, osteomalacia, has recently been reported by Goldthwait, Painter, Osgood and McCrudden.¹ This study was made in a case in which castration was performed for therapeutic purposes, and an opportunity was thus offered for a comparison of the metabolic products before and after the operation. From a chemical study of the food of the patient and the urine and feces it was found that there is a very marked increase in the excretion of calcium, chiefly in the urine, while there is a retention of sulphur and a small amount of magnesium. These results are interpreted as indicating that a decalcification of bony tissue occurs and that the calcium is replaced to a slight extent by magnesium, but chiefly by an organic substance rich in sulphur, similar to but not exactly like normal organic matrix. By castrating during this period of decalcification the process is reversed; that is, calcium is retained and there is a tendency for the sulphur metabolism to correct itself, though this is not very marked. These results agree with those of Neumann, who has also noticed the additional fact that in severe cases, when the disease has lasted a long time, the decalcification process comes to an end, and then castration is without avail in rectifying the metabolic processes. The histologic studies of osteomalacia made by others tend to support such conclusions drawn from chemical data. In sections of bone there is seen a zone of osteoid tissue on the margin of the trabecule, in which may be seen the remains of the bone corpuscles. Along the osteoid tissue in close contact with it is a layer of cells, apparently belonging to the connective tissue type and suggestive of the idea that in some way these cells are concerned in the process of bone disintegration.

Just how the decalcification is brought about in osteomalacia is a problem about which there has been much theorizing and some experimenting, but it still remains unsolved. To lactic acid has been attributed the cause of the decalcifying process because it has been found in the urine. In this disease a decrease in the alkalinity of the blood has been observed, and this has been used to support the acid hypothesis. Lactic acid, however, occurs in the urine in other conditions with no softening of bones, and it does not occur constantly in the urine in this disease; the titration methods used to determine the alkalinity of the blood are not trustworthy and are of little importance, so that there is not much to substantiate the acid theory. Other acids, as carbonic and oxalic acids, have been suggested as playing some part in the process, but there is little or nothing to support such an idea.

The most rational view of the bone changes in osteomalacia appears to be that the normal function of either the marginal cells or bone corpuscles or both is so altered by certain substances, such as an abnormal ovarian secretion, and perhaps under certain circumstances other

1. Am. Jour. Phys., 1905, vol. xiv, p. 389.

substances also, that there results an abnormal absorption of the inorganic constituents. The deposition and absorption of substances depend on the chemical equilibrium of the cell, and only a slight shifting of this either way is necessary to give rise to extensive lesions in the form of osteoblastic or osteoclastic changes.

THE COMING OF AGE OF PHAGOCYTOSIS.

In 1881 two important articles on phagocytosis by Metchnikoff were published, so that it may be considered that this theory has just passed its majority. If at any time in its history a theory may be judged on its merits, it is when it has reached its maturity, and Professor Metchnikoff's recent book on "Immunity" supplies the details on which to base judgment.

Metchnikoff reviews the course of opinion from the first announcement of the theory, when Virchow, with his wonderful capacity for recognizing the truth, even when distinctly novel, was the only prominent pathologist to give it a welcome, to the present day, when practically every one concedes that phagocytosis is the most important element in the production of immunity, and when many consider it to be the origin of the most powerful immunizing forces within the body.

It is not strange that the theory of phagocytosis should have been looked at askance when it was first announced. In his presidential address before the Liverpool meeting of the British Association nearly ten years ago, Lord Lister said: "If ever there was a romantic chapter in pathology, it has surely been that of the story of phagocytosis." That the white cells of the body should array themselves in serried columns at points where bacteria were invading the tissues and at the call of some unknown force be ready to lay down their lives and be thrown off as dead pus cells for the protection of the body was an idea that could scarcely help but appear chimeric. Besides, the originator of this theory was not particularly known in the world of pathology. He was doing his work in Russia and it seemed as though the theory were the result of an almost oriental imagination rather than that of serious long-continued investigation.

Metchnikoff's theory, however, was founded on observation of the most acute and original kind. Consequently it was destined, in spite of many vicissitudes of opinion, not only to hold its own, but gradually to occupy the position of master spirit in the important field of immunity. All sorts of argument have been used against it. At first the writers of the best known text-books on pathology rejected it on *a priori* grounds; men like Baumgartner and Ziegler, and Weigert and Flüge at first refused to consider phagocytosis seriously, but now they recognize its supreme significance. The tracing of the gradual change of opinion of these distinguished

pathologists in the various editions of their text-books is one of the most interesting parts of Professor Metchnikoff's historical sketch of immunity.

It is curiously interesting to find just where in the realms of physiology and pathology the author of phagocytosis considers it to have a proper place. Phagocytosis is entirely in harmony with cellular pathology and co-ordinates our advance in knowledge in the nineteenth century much better than does any other theory of immunity. In the domain of physiology it ranges itself quite readily as one of the phases of the digestive processes within the body. Metchnikoff does not hesitate to say that as a consequence of this theory the study of immunity comes into the chapter on digestion regarded from the general point of view.

Though the subject is treated from a pathologic standpoint, it is only what might be expected from Metchnikoff that practical suggestions should occur here and there, some of which may prove to be of great value. For instance, in the closing chapter, which is a summary of all the work that has been done on immunity in the last twenty-five years, he suggests that phagocytosis may yet prove to be the surgeon's most efficient aid in the prevention of septic complications after operations.

He says: "We may even attempt to increase phagocytosis in surgical operations, especially in those on the peritoneal cavity, by there setting up an artificial aseptic inflammation, by means of various substances, innocuous in themselves, which attract a large number of leucocytes. In laboratory practice, this method is in daily use for the purpose of increasing the resistance of an animal against intraperitoneal injections of various micro-organisms, and Durham has suggested the extension of the same method to human medicine. Certain surgeons have already made attempts in this direction."

The author of the phagocytosis theory well deserves the congratulations of the medical profession on the coming of age of what has become so important a doctrine in the pathologic world.

PREPARATION OF ENDOTOXINS.

There is a small group of bacteria which, when grown in artificial media, produce substances that have marked toxic properties. In the given case this substance may be easily freed from the bacteria by filtration and is usually called the soluble toxin. Such bodies, of which diphtheria and tetanus toxins are typical examples, have received a large amount of study and are fairly well known. When introduced into the animal body there is produced a substance—the antitoxin—which counteracts their effect. The mechanism of the interaction of these bodies is fairly well understood and it is through the application of this knowledge that modern medicine has achieved some of its most successful results.

There is another and apparently larger group of organisms which, when grown on artificial media, do not

1. "Immunity in Infective Diseases," by Elle Metchnikoff. Translated from the French by Francis G. Binnie, University of Cambridge.

produce soluble toxic substances, but which, however, in the infected body give rise to symptoms that indicate the presence of violent toxins. Typhoid and cholera bacilli may be mentioned as typical examples of this class. If cholera bacilli, for instance, are grown for a few days in liquid media and the culture filtrated, the filtrate has practically no toxicity. The bodies of the bacilli, however, even though killed, are highly toxic as a result of their disintegration by the body fluids when introduced into animals. If an old culture which has stood in the incubator for several weeks is examined the toxicity is found to be considerably increased. Evidently, then, the toxic principle resides firmly fixed in the bacterial body; it has been called, therefore, an intracellular toxin or endotoxin. It is of a different character from the soluble toxin, being, as a rule, much less intense and not having the property of causing the production of real antitoxins in the body of the host; at least no antiendotoxins have so far been produced. Because of this fact the application of curative serum-therapy to diseases caused by this class of bacteria has been largely devoid of positive results.

Much work has been done with a view of obtaining these endotoxins from various bacteria in concentrated form for the purpose of producing antibodies that may be of service in the prophylaxis and treatment of the disease. McFadyean claimed that he obtained a toxic body by grinding and extracting typhoid bacilli rendered brittle by the temperature of liquid air, and for this substance he said an antibody could be obtained. It has not as yet been proved of practical value in treating the disease. Wright's method of vaccination in typhoid fever, which has been used so extensively and with apparent success in the British army, consists in the introduction into the body of typhoid bacilli killed by heating to 60 C. The endotoxins are liberated by the action of the body fluids, producing a marked reaction, and there subsequently results the formation of bactericidal substances which protect the individual from a later infection. The use of the products of autolysis of typhoid bacilli has also been suggested by Neisser, and the reaction is said to be less marked.

Besredka¹ has suggested the liberation of the endotoxin *in vitro* by treating the dried typhoid bacilli with normal horse serum for several hours and then separating the fluid from the bodies of the bacilli by the centrifuge. He states that the bodies of the bacilli are much less toxic than before treatment with the serum, while the fluid is distinctly toxic. The former he calls atoxic bacilli, and with them he is able to confer immunity in animals by using them as a vaccine and without any of the deleterious results which occur in using the bacilli before such treatment. The liquid endotoxin

anti-endotoxic serum obtained by injecting typhoid bacilli—living or dead—into the veins of the horse. Besredka in the same manner has obtained the endotoxin for the pest bacillus, and found it likewise to be a fairly thermostable body which is neutralized by an antipest serum.

Slatineanu,² employing the same technic as Besredka, obtained an endotoxin from Pfeiffer's bacillus (*B. influenza*) in such concentration that .5 c.c. injected into the brain of a guinea-pig killed it in sixteen hours with marked lowering of the temperature. Small quantities injected into the peritoneum also produced death with characteristic symptoms.

We give these results as indicative of what is being accomplished by experimental investigators of the problems presented by endotoxins. Whether actual anti-endotoxins have been discovered remains to be seen. This method may provide a means, however, of obtaining certain bodies in a more suitable form for work, and perhaps some interesting results may develop. The use of the so-called atoxic bacilli for immunization recalls Behring's announcement of the therapeutic effect of tubercle bacilli freed from certain toxic and injurious substances.

THE HOUSE FLY.

Two articles have recently appeared which may seem to indicate how the extremes of the pendulum too often characterize scientific presentations. The subject in this particular instance is the part played by the house fly in the causation of tuberculosis. One writer³ attributed to this source so large a proportion of cases of tuberculosis that on sober reflection one must surely regard his views as exaggerated. The other writer⁴ rather vehemently declared that the house fly is almost never an etiologic factor in this disease.

The judicious have here especial reason to grieve, for the propaganda against tuberculosis now being carried on is one which will certainly redound enormously to the well-being and the happiness of mankind if it be based on temperate, just and scientific deductions from accurately observed facts. We emphasize this "if"; for otherwise unreasonable and far-fetched statements, such as must seem absurd to the laity, will certainly prevent the goodly measure of fruition which the present campaign against tuberculosis should rightfully enjoy. We are in the habit of scolding the laity for its phthisiophobia—and our position here is somewhat grotesque; for this fear of consumption is in great measure developed in the lay mind by means of the intemperate and ill-balanced statements of medical men. Exaggeration may carry its point at the bar or in the pulpit; but moderation of statement is an essential—an absolute essential

2. Comp. rend. Soc. de Biol., 1905, vol. xlix, p. 339.

4. T. J. Mays: "The Fly and Tuberculosis," *N. Y. Med. Jour.*, Aug. 26, 1905.

¹ 300-gram guinea-pigs in peritoneal doses of 1.5 c.c., precipitated by alcohol, and is destroyed by heating to 55 C. for fifteen hours. It is also neutralized by an

—of the scientific mind. Undoubtedly, the house fly has been the carrier of tuberculous infection. No one can doubt this who has seen the nutrient film exhibited in the recent Tuberculosis Exhibition in New York City, on which flies that had previously been deposited on tuberculous sputum had walked; colonies of tubercle bacilli developed along the tracks which these flies made on the film. On the other hand, tuberculosis is of course disseminated in other ways than by flies.

The excessive infant mortality and the wide prevalence of typhoid fever would seem to be due in some measure to the *Musca domestica*. Milk, states Dr. J. T. C. Nash,⁵ is one of the favorite foods of flies. Especially in the homes of the poor is this nutritious fluid open to their depredations. Thus is the milk contaminated with the excreta of flies and with the noxious matter clinging to their feet, and here the germs deposited must find a favorable culture medium. Nash has made a series of observations regarding the coincidence of infantile diarrhea with the number of flies. He concludes that milk is liable to pollution even more after delivery to the consumer than before it reaches him. Happily, much attention is now paid to flies in dairies. A measure emphasized by Dr. L. O. Howard is based on the fact that most house flies breed in horse dung; and the stable is generally an accompaniment of the dairy. Farmers and dairymen, therefore, should keep flies from manure pits, a proceeding easy of performance. Thus not only would infant mortality be reduced, but the number of typhoid cases would be decreased. Here, perhaps, may be an explanation of why city dwellers so often return from their vacation smitten with typhoid fever. May not the house fly have been responsible for many cases that have been attributed to "tainted" wells?

In our Spanish war it was abundantly demonstrated that the most careful system of water supply is unsatisfactory if the sewage system is bad and if flies are permitted to pollute the food and drink. One must observe that all the other conditions which produce typhoid—bad sanitation, diet, lowered vitality and the like—exist all the time; while the multiplication of typhoid cases coincides with fly time. With regard to cholera, Chantemesse has demonstrated the rôle played by flies in the dissemination of the specific germ. Fortunately, however, as he has shown, the cholera bacillus in flies loses its virulence after forty-eight hours.

DEGENERATED SYMPATHY.

There is no limit to the extremes to which the professed well-wishers of the race will go. A little while ago we noticed the recommendation of a reforming woman to kill off the incurables, and now comes another one who advises murder of the children of the slums lest they should grow up to future poverty and misery. Perhaps, however, the most notable moral aberration is that of the distinguished ex-Harvard professor, Charles E. Norton, who comes out boldly for making

away with the so-called hopelessly insane, diseased or injured. Professor Norton is a sort of an esthete, and morals and esthetics do not always coincide, in spite of theories. In fact, we have learned to be somewhat suspicious of the moral convictions of those who profess to cultivate the esthetic sense to any extreme, and Professor Norton is apparently not an exception. While his published letter may give some impetus and encouragement to Miss Hall and her followers, it will not command much consideration from sensible people, and certainly not from the mass of the medical profession. He utterly misjudges the motives of physicians in asserting that they are deterred to any extent from following the course he advocates by the mere desire to avoid responsibility or to show their skill in overcoming difficulties. The ethics of the profession are apparently little understood by him and his kind.

CONTRACT PRACTICE.

Medical societies at various points throughout the country are condemning contract practice, more especially that form known as lodge practice, by which certain organizations exploit the medical profession. While the evil in this country is not so great as in Great Britain, it is sufficiently serious to enlist the attention of the profession. A recent instance shows not only the spirit of these organizations, but also affords an example of a thoroughly temperate yet absolutely unanswerable statement of the medical side of the question. A few weeks ago the Shasta County (California) Medical Society unanimously adopted resolutions condemning lodge practice as it there existed and pledging its members to have no professional intercourse with lodge-contract physicians—resolutions which were thoroughly justified by their experience. This called out a series of resolutions from a local benefit society denouncing the medical society's action and claiming fifty years' precedent and all sorts of moral claims for its conduct of the lodge contract medical service, and denying the right of the medical society to have anything to say about it. In reply the medical society shows that its resolutions were not aimed at the existence of fraternal organizations, or even at contract practice generally, provided that reasonable compensation was given. It pointed out that while corporations paid a certain rate, which might not, perhaps, be considered too low, the lodge practice rates were only 10 per cent. of those of the corporations and that, assuming the \$1 a month for each employé provided for by the corporations as reasonable, the fraternal order demanded that the physician should take 90 per cent. of that out of his own pocket for their benefit and serve its members and their families at an average rate of 10 cents a month for each individual. It was only when the lodge placed a valuation on its services comparable to those of the boot-black and peanut vender that the society made its protest. Certainly, if it should be condemned it should only be for its forbearance. It is a curious fact that the majority of these fraternities are largely made up of working men, who are in their organizations wide awake enough to secure every pecuniary advantage in their contracts with those to whom they render service, but are even more zealous, apparently, to take advantage of

5. Journal of the Royal Sanitary Institute.

those whose services they demand. It is certainly time, when conditions are such as existed in this California instance, that the medical profession should take a stand in its own behalf, and it is only by organized effort that this can be successfully done. The case is not a unique one, even in this country, and our British confrères have had many analogous experiences. While human nature is as it is, we must expect injustice if we choose passively to permit it, and that from those who make the highest professions of general charity and benevolence. A professed love for all mankind is, as Thackeray says, a very vague and indefinite sort of virtue, and when the said love and charity are specially found in fellow-members of a lodge they seem to be still more diluted for outsiders. There is no profession that exercises the virtue of charity more than the medical profession, and we would not have it otherwise, but that does not imply the necessity of our unresistingly submitting to gross injustice, such as is inevitably the consequence when lodge practice is unrestrained.

PROFIT IN NEW YORK'S GARBAGE.

If a sanitary measure is cheaper in its execution than an insanitary method, the combination is a pretty strong one, favoring the hygienic method. For years the street-cleaning department of New York City was accustomed to dump garbage in the sea, and as a result the floating portions formed an unsightly and unsavory fringe along the shores of New York City and suburbs, while the heavier parts formed dangerous shoals. A recent report¹ of the present method of disposition shows a profit instead of an expenditure. The heavier portions of the refuse have been used to fill in eighty-four acres of land along the shore, each acre being estimated to be worth \$10,000 (and eighty other acres of less value). Other refuse is sold for salvage and the money received from the salvage contractor runs a lighting plant to illuminate a number of city buildings and public schools. Another portion of the refuse is used as fuel in this lighting plant. Thus was achieved an immense improvement, and the profitable result—representing an income of \$52,000 yearly instead of an expense—is a good example for other municipalities.

THE NOSTRUM EVIL.—The *Kentucky Medical Journal* hopes "that Kentucky doctors will give this . . . whole matter earnest thought, and will arrive at definite conclusions as to their duty in the matter of nostrums. They should give their own journal an active support in this fight which it is waging against this evil, with the assurance that the end is not yet, and that many bitter fights will have to be won before we will be able to free ourselves from these crafty ones, who soothe and flatter us, and behind our backs smile at the guilelessness which permits us to be docilely exploited to their great gain and good. More than this, look over the pile of journals on your table, and when you find an improper thing advertised, write to the journal protesting, and asserting your disapproval; or take other and still more drastic means of assuring editors and publishers that you are awake and alive to their no denunciations."

Medical News

DISTRICT OF COLUMBIA.

Banquet to Dr. Fletcher.—Dr. Robert Fletcher, associate librarian of the Army Medical Library, was entertained at a banquet by the local profession January 11, and presented with a handsome loving-cup as a testimony of his valuable services in this library during the past 30 years. Dr. William W. Keen, Philadelphia, made the presentation speech.

Health of the District.—The report of the health officer for the week ended January 6 shows the total number of deaths to have been 135—white 71, colored 64; births, 118—white 73, colored 45. The following cases of contagious diseases were under treatment at the close of the week: Diphtheria, 30; scarlet fever, 36; typhoid fever, 62, and smallpox, 21.

Therapeutic Society Meeting.—At the annual meeting of the Therapeutic Society of the District of Columbia, January 13, Dr. D. Olin Leech read his annual address as retiring president. The election of officers resulted as follows: President, Dr. Noble P. Barnes; vice-presidents, Drs. Harry A. Robbins and Edgar W. Watkins; recording and corresponding secretary, Dr. Arthur J. Hall; treasurer, Dr. John S. McLain, and censors, Drs. Frank Leech, Charles M. Beall and John W. Chappell.

ILLINOIS.

Hospital Notes.—The addition to the Marietta Phelps Hospital, Macomb, is almost completed. Dr. Samuel C. Stremmel is surgeon-in-chief. Minerva Hospital, erected by Dr. John A. Colbourne at Pontiac, has been opened.

State Board of Charities.—The following have been appointed members of the State Board of Charities: Dr. Frank Billings, Chicago, president; Rabbi Emil G. Hirsch, Chicago; Miss Julia Lathrop, Chicago, and Dr. John T. McNally, Carbondale.

Epidemic Diseases.—Stonington is under quarantine on account of five cases of diphtheria and the public school has been closed. Smallpox cases have been reported to the State Board of Health from Bureau, Greene, Jersey, Kane, La Salle, Logan, McHenry, McLean, Macon and Sangamon counties.

Coroners' Inquests.—During the year ended December 1 the coroner of Cook County investigated 3,482 cases, including 25 cases in which the cause of death was given in the certificate. The nature of the fatalities follows: Natural causes, 1,185; suicides, 453; railway accidents, 355; falls, 221; homicides, 187; burns and scalds, 163; street-car accidents, 137, and other causes, 781.

Civil Service Examinations.—The State Civil Service Commission will hold an examination this month for attendants in the seven hospitals for the insane. This examination will be open to women between the ages of 18 and 45 years, and to men between 22 and 40 years. The subjects on which applicants will be examined and the weights or basis of marking will be: Common school requirements, 3; physical examination, 4, and oral examination as to qualifications, 3. The examining board consists of Dr. Harry G. Hardt, assistant physician at the Illinois Northern Hospital for the Insane, Elgin; Dr. Herbert A. Potts, assistant physician, Illinois Central Hospital for the Insane, Jacksonville, and Miss Nellie Fitzgerald, head nurse, Illinois Eastern Hospital for the Insane, Kankakee.

Personal.—Dr. and Mrs. Benjamin E. Jones, Rock Island, have gone to California for the winter. Dr. Robert C. J. Meyer, has been appointed commissioner of health of Moline. Dr. Franklin E. Wallace has been appointed health officer of Monmouth during the absence of Dr. William H. Wells. Dr. Harry G. Hardt has assumed his duties as assistant physician at the Illinois Northern Hospital for the Insane, Elgin. Dr. Clifford U. Collins, Peoria, was operated on for appendicitis December 23. Dr. James Henry, La Harpe, has retired from practice. Dr. Ernest S. Reedy, Bloomington, has located in Blaine, Wash. Dr. J. Whitefield Smith has been elected president; Dr. John L. Volton, vice-president; Dr. Horace W. Elder, secretary-treasurer, and Dr. Edson Hart, staff representative, of the staff of Brokaw Hospital, Bloomington. Dr. Andrew J. McIntosh, Allendale, is dangerously ill with cerebral hemorrhage. Dr. George A. Sihler, Litchfield, was operated on for appendicitis, December 18.

Chicago.

Smallpox Reappears.—After an interval of several months, a case of smallpox was discovered on the West Side, January 11.

¹ *Scientific American*, Dec. 30, 1905, p. 522.

Memorial Bowlder Placed.—A mammoth bowlder has been placed in Grant Park, by the Chicago Medical Society, in memory of Dr. Samuel Guthrie, the discoverer of the anesthetic properties of chloroform.

Personal.—Dr. Otto W. Lewke, coroner's physician, is seriously ill with septicemia from a postmortem wound.—Dr. Carl Beck has been chosen honorary president of the Society of Former German University Students, at its annual meeting held in New York City, December 21.

Not Illegal to Sell Eucaim.—In the case of Louis Re, arrested on the charge of selling eucaim, the judge held that eucaim is not mentioned in the state poison law, and that the city ordinance forbidding its sale is invalid because the state alone has power to make such prohibition. The defendant was accordingly acquitted.

Deaths of the Week.—The deaths for the week ended January 13 numbered 582, or 20 more than for the previous week, and 40 more than for the corresponding week of 1905. The respective annual death rates per 1,000 were 14.80, 14.31 and 14.19. Of the principal death causes, pneumonia heads the list with 114, followed by consumption with 66; violence, including suicide, 52; Bright's disease, 44, and heart diseases, 40.

Chicago's Health.—The summary of the Health Department for 1905 shows that the death rate for the year was 13.67 per 1,000. Compared with the death rate of other cities of more than half a million inhabitants, the report states that the death rate of Chicago is 9.4 per cent. lower than that of St. Louis; 29.7 per cent. lower than that of Philadelphia; 21 per cent. lower than that of Boston; 25 per cent. lower than that of New York, and 26.9 per cent. lower than that of Baltimore. The death rate of Chicago is also shown to have progressively decreased by decades since 1845, as follows: 40.52, 23.86, 24.11, 20.41, 20.06 and 14.98. During the year 546 cases of smallpox were treated at the Isolation Hospital, with 61 deaths. The typhoid fever death rate was the lowest on record and more than 90 per cent. below that of 1891. The mortality from diphtheria decreased from 13.7 per 10,000 in the decade ending 1894, and 4.9 in the decade ending 1904, to 2.1 per 10,000 in 1905, a reduction of 84.7 per cent. from the rate of the decade prior to the introduction of antitoxin. Pneumonia caused 552 fewer deaths in 1905 than in 1904, a decrease of 15.9 per cent. as compared with the previous year. Only three chronic diseases showed increase: Bright's disease increased 5.9 per cent.; cancer, 2.93 per cent., and heart diseases showed an increase of only 50 more deaths than in 1904. Pneumonia led in the death causes with 3,582, followed by consumption, with 3,203; acute intestinal diseases, with 2,570; heart diseases, with 2,110; Bright's disease, with 2,017; violence, with 1,638; cancer, with 1,191, and nervous diseases, with 1,093. Diphtheria caused 426 deaths; measles, 231; whooping cough, 350; scarlet fever, 79; smallpox, 61; typhoid fever, 320, and yellow fever, 1 death.

INDIANA.

Goes Free.—Dr. Sumner A. Edmonds, Goshen, charged with having performed a criminal operation on Mrs. Anna Darnell, was found not guilty, January 10.

Fined for Illegal Practice.—Dr. Stephen A. Spees, Terre Haute, charged with practicing medicine without a license, was found guilty, January 5, and fined \$25 and costs.

New Hospital.—Hon. D. D. Dykeman has agreed to donate to Logansport a hospital for the use of its citizens, in memory of his wife, and to be known as the Mary Dykeman Hospital. It will build a hospital to cost \$75,000 and endow it with \$100,000.

Medical Course at State University.—The trustees of Indiana University, Bloomington, have decided to make its pre-medical course, a full medical course for four years, and to confer degrees. The reorganized school of medicine will begin its work next fall.

Hospital Dedicated.—The reconstructed and enlarged St. Elizabeth's Hospital, Lafayette, was dedicated with imposing ceremonies by Bishop Aldering, December 31. The addition was erected at a cost of more than \$50,000, and doubles the capacity of the institution.

Fountain County Society Meeting.—The January meeting of this society was held at Covington. The following officers were elected: President, Dr. Francis A. Shoaf, Veedsburg; vice-president, Dr. Albert C. Holley, Attica; secretary, Dr. George Rowland, Covington, and censors, Drs. Marshall Petet, Veedsburg, Charles J. Finney, Attica, and Walter H. Ross, Veedsburg.

Personal.—Dr. John H. Ross, Kokomo, has gone to Winter Haven, Fla.—Dr. Hugh A. Cowing, Muncie, has been reappointed secretary of the Delaware County Board of Health.—Dr. William H. Daniel, Corydon, has been appointed secretary of the Harrison County Board of Health.—Dr. Edwin O. Harrold, Marion, has been appointed local surgeon for the Big Four and Pennsylvania systems.—Dr. Stanley W. Edwins, Elwood, is critically ill.—Dr. Morton J. Compton, Evansville, has been appointed secretary of the Vanderburg County Board of Health, vice Dr. Willis S. Pritchett.—Dr. James D. Hillis, Lafayette, has been appointed secretary of Tippecanoe County Board of Health.—Dr. Daniel B. Cain has been appointed police surgeon of Evansville.—Dr. William M. Wright, Indianapolis, in a street-car accident, January 3, suffered severe lacerations of the face.—Dr. Charles E. Barnett, Evansville, returned from Vienna, January 15.—Dr. L. L. Williams has been appointed surgeon at Brazil for the C. & E. I. R. R.—Dr. Hezekiah C. Doster, Poneto, suffered a severe cerebral hemorrhage, January 3.

MARYLAND.

First-Aid Instruction.—The Baltimore & Ohio school for instruction in first aid to the injured was opened at Cumberland January 8, under the charge of Drs. John A. Doerner and L. S. Stitley of the relief department, assisted by local surgeons. Trainmen, foremen and minor officials are required to attend.

To Regulate Sale of Narcotics.—The attorney-general has drafted a bill to regulate the sale of narcotic drugs. It applies to cocaine, eucaim and morphin, but not to opium. The burden of proof is to be on the accused to show that he did not know or could not have ascertained that the article furnished contained prohibited drugs.

Appointments.—Dr. Armfield F. Van Bibber, Belair, has been appointed physician to the Harford County Almshouse, and the following have been appointed vaccine physicians for that county: First district, Dr. Charles E. Roth, Edgewood; second district, Dr. Jay H. Stier, Perryman; third district, Dr. E. Hall Richardson, Belair; fifth district, Dr. Walter B. Kirk, Darlington, and sixth district, Dr. W. L. Hopkins. Dr. Frank P. Smithson, Forest Hill, has been appointed subregistrars of the third district.

State Hospital Reports.—The tenth annual report of the Springfield State Hospital for the insane for the year ended Oct. 1, 1905, shows that 166 patients were admitted and 129 were discharged, paroled and died, leaving 644 remaining in the institution. The annual death rate was 7.57 per 1,000. Two more hospital buildings, a new dining-room, kitchen and isolation building are needed.—The one hundred and eighth annual report of Maryland Hospital for the Insane, Spring Grove, for the year ended Oct. 31, 1905, shows that only 61 patients were admitted, the smallest number in the history of the institution and due to its crowded condition. There were 620 patients under treatment during the year, of whom 30 were discharged, 18 as cured, 7 improved and 5 unimproved, and 31 died. The number now in the hospital is 559. The net cost of maintaining the hospital was \$113,040, and the cost per capita \$201.50.

Baltimore.

Beriberi.—There is a case of beriberi in a Norwegian sailor at the City Hospital. The man came on a ship from Brazil. A similar case occurred at the City Hospital last year.

Portrait of Dr. Hurd.—The past and present house officials of the Johns Hopkins Hospital are to have a lifeseize portrait painted of Dr. Henry M. Hurd, superintendent. It will be hung in the administration building.

Personal.—Dr. J. Hall Pleasant is ill with typhoid fever.—At the Johns Hopkins Hospital Dr. C. P. Emerson has been appointed resident physician, vice Dr. Rufus T. Cole, resigned. Dr. Cole has been appointed associate in medicine and Dr. Josiah M. Stenmons, associate in obstetrics. Dr. Roger Morris has been appointed assistant resident physician and Dr. J. A. Caldwell has resigned as assistant gynecologist.

MASSACHUSETTS.

Want Bowditch Back.—An earnest effort is being made to induce the governor and council to revise the action of the trustees of the Rutland Sanitarium in displacing Dr. Vincent V. Bowditch as visiting physician.

Board of Insanity Report. The Massachusetts State Board of Insanity states that it has under its care 10,153 insane persons, 4,832 men and 5,321 women, or one to every 296 of the general population. It asks that accommodations be pro-

vided for 200 more. The extreme overcrowding reported last year has been relieved and will continue so if the state will furnish this additional room each year.

Brigham Hospital Announcement.—The directors of the Brigham Hospital for incurables announces that the accumulated income now amounts to \$277,884.47 and that it is, therefore, intended to proceed with the plans and erection of a hospital large enough to care for 200 patients. This will not be primarily for tuberculous patients, but chronic diseases like cancer, paralysis, etc., will probably constitute the larger number. The location is to be on the top of Parker Hill, Roxbury.

Vital Statistics.—The vital statistics for Massachusetts for 1904 as reported to the legislature, show that with a population of 2,805,346 there were 75,014 births, 25,993 marriages and 48,482 deaths. The birth rate was the lowest since 1879, while the number of marriages was greater than any year since 1850, except 1903. The death rate was 15.76 per 1,000, the lowest since 1851. Deaths among infants under 1 year old were 9,922, 74 less than the average of the past 10 years. There was a marked decrease in the deaths from infectious diseases, specially pertussis, scarlet fever, measles and diphtheria.

Personal.—Dr. Walter Renssen Brinckerhoff, assistant pathologist at Harvard Medical School, who has already made a name for himself as assistant to Dr. William Councilman in the search for the germ of variola, having carried out supplementary work in the government laboratories at Manila and subsequently studied the plague in the Transcaucasus, has been appointed pathologist in charge of the new hospital and laboratory for the study of leprosy on the island of Molokai, Hawaii.—Dr. Fred B. Lund, Boston, has been appointed one of the board of trustees of the Melfield Insane Hospital.

NEW YORK.

Violations of Pure-Food Law.—State Commissioner Weiting during the last year referred to Attorney-General Mayer 507 cases of violations of the agricultural law, including the following: Impure milk, 230; impure butter, 29; impure food, 126. There are 368 other cases under investigation.

Infected Milk.—As the result of information from Health Officer I. Adelbert Nix of Binghamton that milk had been shipped to New York City from a dairy near Binghamton which was infected with scarlet fever, the State Department of Health will direct the Board of Health of New York City to prevent the receipt of this milk. Dr. Nix threatens to prefer charges against the health officer in the town where the dairy is located, alleging that he failed to enforce quarantine on the infected premises.

New York City.

Yerkes Hospital Will be Built.—The hospital in the Bronx provided for by the will of the late Charles T. Yerkes will be begun as soon as the estate is settled, instead of waiting until the death of Mrs. Yerkes, as provided by the will.

Vital Statistics of Queens.—There were in this borough for the year 1905, 4,355 births, 3,191 deaths and 1,092 marriages. Of the various causes of death consumption led with 310. There were 611 coroner's cases, 413 accidentals or homicides, 56 were suicides, and 10 from sunstroke.

Health Board Wants More Money.—At the first meeting of the new board of estimate, which was held January 12, the Department of Health asked for \$135,000. One of the items called for \$15,000 for drugs and antitoxin. The matter was referred to Mr. Metz, who is a manufacturer of antitoxin.

Contagious Diseases.—There was reported to the sanitary bureau for the week ended December 30, 798 cases of measles, with 12 deaths; 348 cases of diphtheria, with 38 deaths; 365 cases of tuberculosis, with 163 deaths; 183 cases of scarlet fever, with 6 deaths; 36 cases of cerebrospinal meningitis, with 16 deaths; 45 cases of typhoid fever, with 7 deaths, and 117 cases of variella.

Large Hospital Collections. At the annual meeting of the Hospital Saturday and Sunday Association, January 8, it was reported that the Woman's Auxiliary would present a fund larger than that of last year, which was \$12,000. The collection in general premises to be the largest in the history of the association. It is thought that it will exceed \$100,000, as against \$92,000 of last year.

No Expert Fees for City Physicians. The assistant district attorney, when recently urged to have a prisoner examined as to sanity, said that whenever such a request was made the doctors posed as experts and put in a bill. Judge Cowing,

who had ordered the examination, said that the city physicians were on salary and that such services would have to be rendered without pay in the future.

Pasteurize All Milk.—The necessity for pasteurizing the entire milk supply of large cities is being kept constantly before the public by the daily papers. It is urged that this work should become a function of the municipality. Nathan Strauss, who has done so much of this work for New York, also urges the importance of the work, and says that while the entire work would transcend the bounds of private effort, in the budget of the government it would be but a small item, which could be met easily by the taxpaying population.

Beth Israel Hospital.—At the annual meeting of the association governing this hospital four new directors were elected. The report showed that during 1905 the hospital received \$84,133.31 and spent \$81,375. Since October 1 the hospital has received \$20,000 in subscriptions, Nathan Hermann subscribing \$5,000 on condition that \$10,000 more be obtained. The directors raised \$15,000, the largest gift coming from the estate of Solomon Baehrach, \$5,000. During the year the hospital treated in all 45,573 persons.

Object to Sanitarium.—A committee of business men of Staten Island called on Charities Commissioner Hebbard at Bellevue January 8 to protest against the proposed tuberculosis sanitarium at Port Richmond. The committee held that the climate of Staten Island was unsuited for this purpose and that the coming of 800 consumptives would threaten the health of the community, and depreciate the value of property in the vicinity. The complaint will be considered and a decision made known within a reasonable length of time.

Health Department Methods Criticized.—A case came to trial recently in which the defendant had been indicted under sanitary laws for keeping his premises in a filthy condition. The Board of Health had no record that the defendant had been notified and consequently Recorder Goff directed that the jury acquit him, and scored the Health Department for allowing its subordinates to initiate proceedings and to issue orders themselves without the slightest regard to the forms of law or without the knowledge of the heads of the department. Investigation showed that the Health Department had kept no records of such proceedings during the past eight years. It was recommended that some system be introduced that would be in conformity with the plain requirements of the law.

Cartwright Lectures.—These lectures, given under the auspices of the Alumni Association of the College of Physicians and Surgeons, will be given this year in the New York Academy of Medicine, January 25 and 29, and February 2. Baron K. Takaki, surgeon general (reserve) of the Japanese Navy, will deliver them, and he has selected as a title "Military and Naval Sanitation Experiences of the Late Japanese-Russian War." He studied medicine in England and was graduated from St. Thomas Hospital with honors. During his time of service in Japan he has busied himself in thoroughly reorganizing the sanitary and medical systems of the new Japanese navy. Up to the recent Japanese-Chinese war he was surgeon general, Japanese navy, and to his energy and genius are to be attributed, in large part, the wonderful results attained by the Japanese navy.

NORTH CAROLINA.

New Sanatorium.—The new sanatorium "Cragmont," for tuberculosis at Black Mountain, 11 miles above Asheville, is nearing completion and will be open about February 1.

Banquets.—The Haywood County Medical Society, with guests from Jackson and Swain counties, were the guests at a complimentary dinner in honor of the society at Waynesville, by Dr. J. Howell Way, January 8.—The Iredell-Alexander County Medical Society held its annual dinner early in January, at Statesville, with a goodly attendance.—The members of the Wilson County Medical Society were the guests of Drs. Charles Moore, Albert Anderson and E. Thomas Dickenson at a complimentary banquet January 4 at Wilson. A number of visiting physicians from adjoining counties were present.

Stand for Five-Dollar Fee.—The Caldwell County Medical Society January 1 adopted the resolutions recommended for adoption by the county societies at the 1905 session of the State Medical Society at Greensboro, fixing the insurance examination fee at \$5 for all regular old-line insurance companies. A large number of other counties which had previously not taken action on this matter, have since done so, and many physicians think the indications are that, unless insurance companies wish to pay \$5 for every insurance examina-

tion regardless of the amount of the policy asked for, they will not be able to secure examiners in the ranks of the regular medical profession.

PENNSYLVANIA.

Philadelphia.

Beriberi Here.—The British steamship *Andora*, from Chile, was quarantined at Marcus Hook, January 9, on account of a case of beriberi and three other suspected cases, which were placed in the detention hospital at the quarantine station. The victims were Chinese sailors.

Blockley Advisory Board. Dr. W. M. Late Coplin, director of health and charities, announced, January 11, the appointment of an advisory staff for Blockley. The staff includes Drs. Alfred Stengel, Charles H. Frazier, Lawrence F. Flick, William L. Rodman, S. Solis-Cohen and Lewis W. Steinbach.

Fighting Nostrums.—A vigorous step in the crusade against nostrums was inaugurated at the meeting of the County Medical Society, January 10. Resolutions were adopted by the society against physicians who use medicines of secret composition, against all journals which print certain nostrum advertisements, and against the United States patent office and postoffice department. A full report is given on page 218.

Personal.—Dr. and Mrs. Henry M. Fisher sailed for Europe January 8.—Dr. Edward E. Montgomery was elected president, and Dr. Charles W. LeFever, secretary, of the Ohio Society, at Philadelphia, January 11.—Dr. Wilford W. Hawke, chief resident physician of the insane department of the Philadelphia Hospital, has resigned.—Dr. W. Reynolds Wilson gave a dinner in honor of Dr. Robert T. Morris, New York City, January 18. In the evening Dr. Morris addressed the gynecologic section of the College of Physicians.

Health Report.—The total number of deaths reported for the week aggregated 582, as compared with 536 reported last week, and 500 reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 23; measles, 17; whooping-cough, 4; diphtheria, 16; meningitis, 4; cancer, 28; apoplexy, 24; heart disease, 64; acute respiratory diseases, 101; enteritis, 16; appendicitis, 3; Bright's disease, 41; premature birth, 17; suicide, 1; accidents, 15, and marasmus, 4. There were 416 cases of contagious disease reported, with 40 deaths, as compared with 341 cases and 36 deaths reported last week. There were 262 new cases of typhoid fever with 23 deaths, the largest number of typhoid fever cases reported in any one week since the outbreak last spring. The disease prevails generally throughout the city, and only three wards are wholly free from it. Measles prevails throughout the city to an alarming extent. There were 431 new cases reported as compared with 353 reported last week, and 17 deaths resulted from this so-called simple affection.

The Death Rate in 1905.—According to the report prepared by Dr. Alexander C. Abbott, chief of the bureau of health, the health of the city during 1905 was exceptionally good, there being 1,200 deaths less than during the previous year. The proportion of deaths to the population was 17.25 per 1,000 for last year and 18.44 for 1904. The total number of deaths from all causes was 21,807. The principal causes of death, compared with the previous year, were as follows:

	1905.	1904.
Pneumonia	2,591	3,361
Tuberculosis, lungs	2,823	3,107
Other forms of tuberculosis	492	295
Typhoid fever	689	744
Diphtheria	361	542
Scarlet fever	60	201

The authorities believe that the open winter was responsible for the low mortality from lung trouble during the latter part of 1905, and that the decrease in the number of cases of all transmissible diseases was due to the better methods of the bureau of health, covering the fumigation and disinfecting of all premises where cases of such disease occurred.

VIRGINIA.

Personal.—Dr. S. R. Jordan of Virgiliana, when returning from a call, was thrown from his buggy and painfully injured. He was found lying in the roadside two miles from home, with his elbow dislocated and head badly lacerated.

GENERAL.

Pathologist for Leper Settlement in Hawaii.—Dr. W. R. Brinkerhoff of the Harvard Medical School, has been appointed pathologist in charge of the new hospital and laboratory at the government experiment station in the leper settlement on the island of Molokai.

New Journals.—The *Bulletin of the Pharmaceutical Association* is a new publication, and the first number makes a very creditable appearance. We wish it success, and trust that this organization will take its stand on present-day subjects, realizing its mission. If this body does not stand for the best in pharmacy, then there is none that does.—The *Albionist Clinic* has changed its name to the *American Journal of Clinical Medicine*, and is somewhat enlarged and has additional members on its editorial staff. As we announced at the time of the fire which destroyed its plant, it proposes to cover a larger field than heretofore. We wish it success.—The *New England Albionist* is a new journal, hailing from Milford, Mass.

Government Exposes Nostrums.—The annual report of the chief of the bureau of chemistry of the Department of Agriculture includes an account of the work of the bureau in aiding the Postoffice Department in investigating various nostrums. Many have been found to be fraudulent and many injurious by reason of the presence of cocaine, morphia, chloral, or a large percentage of alcohol. THE JOURNAL has published the details of some of these investigations, and they will show the character of the work. Inspection of exported and imported foods has been continued, as well as physiologic experiments with food preservatives. Seven thousand three hundred and thirty-eight samples were analyzed, including 3,750 samples of imported foods, 2,579 samples for the hygienic table, and 1,009 miscellaneous samples.

Prevention of Importation of Smallpox from Canada. Acting Assistant Surgeon Young reports the precautions taken on the Canadian border to prevent the importation of smallpox during the present epidemic. Trains were inspected, susceptible individuals vaccinated, cars disinfected and all other necessary steps taken to prevent the entrance of the disease. Admission was refused to some persons because of suspected contact with smallpox at Tracy or Fredericton Junction, on line of Canadian Pacific Railroad between St. John and Vanco-boro, or because of positive knowledge that proper disinfection had not been done in the houses from which the individuals came and in which smallpox had occurred. The present epidemic is especially dangerous because of its mild character in the early stages, many persons concealing the disease so that in a large percentage of cases no disinfection had been done, and in many cases the health officials have no knowledge of its existence. Dr. Young states that three times within two weeks persons with face and hands partially covered with sores have appeared at Fredericton Junction from points in surrounding country, and of these only one had broken quarantine.

CANADA.

Statistics of St. John, N. B., for 1905.—During the year 1905 968 births were recorded in the city of St. John, N. B., and 472 marriages. These returns show an increase of 8 births and 42 marriages over 1904.

Montreal Weekly Vital Statistics.—There were 68 deaths in Montreal during the first week of 1906, the lowest mortality for many years. The average weekly death rate in Montreal is 125. There was only one death from a contagious disease.

Vaccination in Toronto.—One of the members of the Toronto board of education is calling for opinions from citizens looking toward the abolition of compulsory vaccination among the school children of that city. The medical health officer advises that instead of abolishing vaccination, it should be extended to include the separate schools in the city.

Margaret Scott Nursing Mission, Winnipeg.—During December, 1905, the nurses of the Margaret Scott Nursing Mission of Winnipeg made 1,003 visits, which show that the work of the mission has nearly doubled since 1904, when only 528 visits were made. Two hundred and ninety-one visits were paid to typhoid fever patients and 186 to obstetrical cases.

Annual Meeting of the Canadian Association for the Prevention of Tuberculosis.—The executive council of the Association for the Prevention of Tuberculosis in Canada met in Ottawa, January 8. It was resolved to hold the next annual meeting in Ottawa in the last week in March, at a date acceptable to the governor-general. Dr. A. J. Richer of Montreal is to deliver an illustrated lecture on consumption at the annual meeting. The question of how the dominion government can best assist in stamping out this plague in Canada, will be submitted to the minister of agriculture at an early date by the president of the association, Senator Edwards.

FOREIGN.

Chair for Social Medicine.—The medical faculty of the University of Bonn, Germany, has created a professorship of social medicine. The first incumbent is to be Professor Rump, until recently director of the General Hospital at Hamburg, but now professor of internal medicine at Bonn.

Death from X-Ray Injury.—The death is reported from Paris of Mr. A. Radiguet, one of the best known designers, makers and demonstrators of instruments for application of the Roentgen rays to medicine. He was chairman of the committee in charge of the exhibition of radiotherapy at the international expositions at Paris, St. Louis and Liège last year. In his constant work with the x-rays, an x-ray burn of the right arm resulted in gangrene, which proved fatal after months of suffering.

Medical Inspection of Schools in Berlin.—The medical inspectors of the schools at Berlin have recently published a detailed report of their work during 1904-5. Each inspector has 127 classes, that is, 8 or 9 schools, to supervise, more than four times as many as in any other German city. The report shows the inestimable benefit of medical inspection from many standpoints. It was found that in one school 31.9 per cent. of the girls and 34.4 per cent. of the boys were habitually drinking beer every day, while 1.8 per cent. of the girls and 4 per cent. of the boys took alcoholic drinks. The development of nervous affections during school life is also confirmed by the report.

Quarantine Facilities in Northern Brazil.—The health officer of the republic, who has just returned from an inspection of quarantine methods and facilities and of the way in which health regulations are observed in northern ports of Brazil, expresses himself in his report as unsatisfied with the result of his inspection. He states that he intends to petition the government to provide the necessary money for the purchase of such indispensable appliances as will secure disinfection establishments, isolation hospitals and disinfecting launches for the fumigation of ships. He reports that the general health of the northern ports is good, but that there is a good deal of smallpox and yellow fever in Manaus, and that the latter malady is prevalent in Belém, the port and capital of Para.

What Shall We Call Schaudinn's Pale Pseudo-Spirochete?—Schaudinn has announced that the *Spirochæta pallida* discovered by him has certain features which class it apart from spirochetes and also from spirilla. He is convinced that it is a new species, and, as mentioned in these columns on page 1992, he suggested the name *Spirocnema* for it. He has since learned that this name has been appropriated for a mollusc and for a flagellate, and he now offers the term *Treponema* to designate his pseudo-spirochete. A suggestion has recently been made in this country to call it the *Micro-spirocnema*, but Schaudinn has the priority, and his term is shorter. It now seems that some of the other so-called spirochetes in reality have no claim to this title. The *Semaine Médicale* remarks in regard to Schaudinn's, that even if we accept his name, *Treponema pallidum*, it will be many a day before clinicians refer to syphilis as "treponemiasis." There has been some confusion in regard to the spelling of spirochete. Spirochæta is the historical term, as first applied by Ehrenberg seventy years ago, but spirochete conforms better to the Greek derivation, and is the one now used by the Germans.

Fancy Dress Ball of the Paris Internes.—One of the features of medical life in Paris among the younger set is the annual *bal de Rintintin*, given in the heart of the Latin quarter. The procession of floats representing the various hospitals is reviewed by a committee of prominent physicians and surgeons, artists and theatrical managers. The first prize at the recent ball was awarded to the St. Antoine Hospital for its representation of the "History of Cholera." First came India, personified by a beautiful maiden, followed by the gilded form of the god Vishnu, brandishing the symbolic bannion culture medium. Then came with great flourish of trumpets and red and green fires, a gorgeous giant strutting on an inaccessible crag, this car being labeled: "The Time Cholera, the Cholera Descending the Russian Rivers." Lariboisière Hospital, with its representation of a glimpse into Hades, and the Charité Hospital, with its "Vaselinade," shared the second prize. Beaujon's Hospital float was a tableau representing Abel Faivre's famous painting, "The Amputation," a white-haired physician amputating the chest of a fair patient. The float of the new Aubervilliers Hospital showed a cart drawn by real oxen and other features of a native African village, all in the clutch of sleeping sickness. The *Journal de Médecine* for December 25 gives a description of the ball.

Pharmacology

Endorsement of Propaganda for Common Sense in Therapeutics.

Dr. Albert M. Eaton, Philadelphia, under date of December 26, writes:

"I thank those in authority for the protection given to us medical men throughout the United States by the work of the Council on Pharmacy and Chemistry. THE JOURNAL is doing good work for all of us in protecting us from schemes and fakes in and out of the profession."

Dr. J. A. Pettit, Portland, Ore., writes:

"I wish to congratulate you on the campaign you are conducting against nostrums. The profession has been 'used,' and an undue advantage taken of the gullibility of its less sagacious members. The result of your efforts along this line will be far reaching, not only in checking the chaos into which modern therapeutics has been gradually drifting, but also in bettering present existing conditions."

Dr. J. H. Ball, Crystal Falls, Texas, writes that he is greatly pleased with the work being done by THE JOURNAL in endeavoring to bring the profession to ethical terms.

Dr. C. E. Duncan, Flora, Ill., writes:

"I am with you heart and soul in your fight on nostrums. Also let me express my gratitude to you for opening my eyes on this important question. I am 'young yet' and have not erred very much in the use of these 'ethical' products. However, but for the 'news' you have printed I know I would have been drawn into the net of 'eloquent' drug salesman."

Dr. J. E. E. Olander, St. Paul, writes:

"Let the good work against poor drugs go on. We appreciate it. The special article is just what we need."

COUNTY SOCIETIES TAKE ACTION.

The Westmoreland County (Pa.) Medical Society, at its December meeting, passed resolutions commending the action of the American Medical Association in establishing a Council on Pharmacy and Chemistry to investigate non-official drugs and medical preparations, and expressing its hearty approval of the action THE JOURNAL has taken in regard to nostrums. The society also commended the work of *Collier's Weekly* and the *Ladies' Home Journal* in exposing the evils of "patent medicines."

Similar resolutions were passed by the Auglaize County (Ohio) Medical Society at its December meeting, by the Nacogdoches County (Texas) Medical Society and by the Northwest Branch of the Chicago Medical Society. The last-mentioned society in addition asked each member to refrain from prescribing proprietary medicines in any case in which it is possible to use the official preparations.

At a meeting held Jan. 10, 1906, the Philadelphia County Medical Society adopted the following resolution:

Resolved, That this society considers it highly unethical and improper for physicians to prescribe or to sanction the use of medicinal agents whose formula and composition are kept secret or concealed; it deprecates the manufacture and sale by pharmacists of nostrums of all kinds; it advises the public against the use of all so-called "patent medicines" and nostrums; it expresses its cordial appreciation and hearty endorsement of the action of the American Medical Association in creating a Council on Pharmacy and Chemistry, and of the officers of the Association, particularly the editor of THE JOURNAL of the Association, in their efforts to exclude advertisements of nostrums from the columns of THE JOURNAL and for their campaign against the nostrum evil; it acknowledges its obligation to and bespeaks the hearty support of those brave lay journals that have done so much to arouse popular and professional sentiment against the use of nostrums by exposing the character of the promoters of this nefarious traffic and the composition of their products; it urges on all editors and publishers, lay and medical, the exclusion from their columns of advertisements of nostrums and furtherance of the crusade against their use; it urges all physicians to refrain from subscribing to and publishing their scientific papers in medical journals that accept advertisements of nostrums; it recommends the appointment by the president of a committee of three to communicate in person and by correspondence with editors and publishers for the purpose of securing their cooperation in the present crusade; it calls the attention of the medical schools to the necessity of training their graduates more fully in the materia medica and in the art of pharmacy, and of pointing out the dangers from the use of nostrums; it heartily endorses the bill for the prevention of

the adulteration and misbranding of foods, drugs, medicines and liquors, now pending or shortly to be introduced in the United States Senate; it urges on the Legislature of the State of Pennsylvania the enactment of laws supplementing the contemplated action of the Federal Government; it condemns the granting by the United States Patent Office of copyright trade-mark registration to the class of nostrums; and by the United States Postoffice of the use of the mails for the exploitation of these nostrums; it requests members of the medical profession to make report of all cases of injury, death or drug habit due to the use of nostrums; it desires to give the widest publicity in both the medical and the lay press to the foregoing resolutions embodying its views on the nostrum evil as adopted, and asks that a committee of one be appointed to promulgate these resolutions.

Not Now Members of the Proprietary Association.

Messrs. Schieffelin & Co. ask us to announce that they have withdrawn from the Proprietary Association of America. They claim that their membership in the Association was merely nominal, and came about through their wholesale drug business, entirely apart from their pharmaceutical department.

Messrs. E. Fongera & Co. also announce that they have withdrawn from the Proprietary Association.

Messrs. Smith, Kline & French Co., Philadelphia, write that they were formerly members of the Proprietary Association, but that they have resigned.

PREYING ON THE INCURABLES.

Samuel Hopkins Adams' Fifth Article in the Series on the Great American Fraud.

Under the title of "Preying on the Incurables" appears the fifth installment of Samuel Hopkins Adams' article on the Great American Fraud in *Collier's Weekly* for January 13. We copy below part of the article, but the illustrations which accompany it are not the least important part of the presentation of the subject:

Incurable disease is one of the strongholds of the patent medicine business. The ideal patron, viewed in the light of profitable business, is the victim of some slow and wasting ailment in which recurrent hope inspires to repeated experiments with any "cure" that offers. In the columns of almost every newspaper you may find promises to cure consumption. Consumption is a disease absolutely incurable by any medicine, although an increasing percentage of consumptives are saved by open air, diet and methodical living. This is thoroughly and definitely understood by all medical and scientific men. Nevertheless there are in the patent medicine world a set of harpies who, for their own business interests, deliberately foster in the mind of the unfortunate sufferer from tuberculosis the belief that he can be saved by the use of some absolutely fraudulent nostrum. Many of these consumption cures contain drugs which hasten the progress of the disease, such as chloroform, opium, alcohol and hashesh. Others are comparatively harmless in themselves, but by their fervent promises of rescue they delude the sufferer into misplacing his reliance and forfeiting his only chance by neglecting those rigidly careful habits of life which alone can conquer the "white plague." One and all, the men who advertise medicines to cure consumption deliberately traffic in human life.

Certain members of the Proprietary Association of America (the patent medicine "combine") with whom I have talked have urged on me the claim that there are firms in the nostrum business that are above criticism, and have mentioned H. E. Bucklen & Co. of Chicago, who manufacture a certain salve. The Bucklen salve did not particularly interest me. But when I came to take up the subject of consumption cures I ran unexpectedly on an interesting trail. In the country and small city newspapers there is now being advertised lavishly "Dr. King's New Discovery for Consumption." It is proclaimed to be the "only sure cure for consumption." Further announcement is made that "it strikes terror to the doctors." As it is a morphin and chloroform mixture, "Dr. King's New Discovery for Consumption" is well calculated to strike terror to the doctors or to any other class or profession, except, perhaps, the undertakers. It is a pretty diabolical concoction to give to any one, and particularly to a consumptive. The chloroform temporarily allays the cough, thereby checking nature's effort to throw off the dead matter from the lungs. The opium drugs the patient into a deceived cheerfulness. The combination is admirably designed to shorten the life of any consumptive who takes it steadily. Of course, there is nothing on the label of the bottle to warn the purchaser. That would decrease the profits. The makers of this beneficent preparation are H. E. Bucklen & Co. of Chicago.

Chloroform and Prussic Acid.

Another "cure" which, for excellent reasons of its own, does not print its formula, is "Shiloh's Consumption Cure," made at Leroy, N. Y., by S. C. Wells & Co. Were it to publish abroad the fact that it contains, among other ingredients, chloroform and prussic acid, the public would probably exhibit some caution in taking it. Under our present lax system there is no warning on the bottle that the liquid contains one of the most deadly of poisons. The makers write me:

"After you have taken the medicine for awhile, if you are not firmly convinced that you are very much better, we want you to go to your druggist and get back all the money that you have paid for Shiloh."

But if I were a consumptive, after I had taken "Shiloh" for a while I should be less interested in recovering my money than in getting back my wasted chance of life. Would S. C. Wells & Co. guarantee that?

Morphin is the important ingredient of Dr. Bull's Cough Syrup. Nevertheless, the United States Postoffice Department obligingly transmits me a dose of this poison through the mails from A. C. Meyer & Co. of Baltimore, the makers. The firm writes me, in response to my letter of inquiry:

"We do not claim that Dr. Bull's Cough Syrup will cure an established case of consumption. If you have gotten this impression you most likely have misunderstood what we claim. . . . We can, however, say that Dr. Bull's Cough Syrup has cured cases said to have been consumption in its earliest stages."

Quite conservative this. But A. C. Meyer & Co. evidently don't follow their own advertising very closely, for around my sample bottle (by courtesy of the Postoffice Department) is a booklet, and from that booklet I quote:

"There is no case of hoarseness, cough, asthma, bronchitis or consumption that *can not* be cured *speedily* by the proper use of Dr. Bull's Cough Syrup."

If this is not a claim that Dr. Bull's Cough Syrup "will cure an established case of consumption," what is it? The inference from Meyer & Co.'s cautious letter is that they realize their responsibility for a cruel and dangerous fraud, and are beginning to feel an uneasiness about it, which may be shame or may be only fear. One logical effect of permitting medicines containing a dangerous quantity of poison to be sold without the poison label is shown in the coroner's verdict herewith printed. In the account of the Keck baby's death from the Dr. Bull opium mixture, which the Cincinnati papers published, there was no mention of the name of the cough syrup. Asked about this, the newspapers gave various explanations. Two of them disclosed that they had no information on the point. This is contrary to the statement of the physician in the case, and implies a reportorial laxity which is difficult to credit. One ascribed the omission to a settled policy and one to the fear of libel. When the coroner's verdict was given out, however, the name of the nostrum got into plain print. On the whole the Cincinnati papers showed themselves gratifyingly independent.

Another case of poisoning from this same remedy occurred in Morocco, Ind., the victim being a 2-year-old child. . . .

Absolutely False Claims.

A curious mixture of the cautious, semi-ethical method and the blatant claim-all patent medicine is offered in the Ozomulsion Company. Ozomulsion does not, like the "cures" mentioned above, contain active poisons. It is one of the numerous cod-liver-oil preparations, and its advertising, in the medical journals at first and now in the lay press, is that of a cure for consumption. I visited the offices of the Ozomulsion Company recently and found them duly furnished with a regular physician, who was employed, so he informed me, in a purely ethical capacity. There was also present during the interview the president of the Ozomulsion Company, Mr. A. Frank Richardson, former advertising agent, former deviser of the advertising of Swamp-Root, former proprietor of Krautonic and present proprietor of Slocum's Consumption Cure, which is the "wicked partner" of ozomulsion. For convenience I will put the conversation in court report form, and, indeed, it partook somewhat of the nature of a cross-examination:

Q.—Dr. Smith, will Ozomulsion cure consumption?

A.—Ozomulsion builds up the tissues, imparts vigor, aids the natural resistance of the body, etc. Goes into a long explanation in the manner and style made familiar by patent medicine pamphlets.

Q.—But will it cure consumption?

A.—Well, without saying that it is a specific, etc. (Passes to an instructive, entertaining and valuable discussion on the symptoms and nature of tuberculosis.)

Q.—Yes, but will Ozomulsion cure consumption?

A.—We don't claim that it will cure consumption.

Q.—Does not this advertisement state that Ozomulsion will cure consumption? (Showing advertisement.)

A.—It seems to.

- Q. Will Ozomulsion cure consumption?
 A. In the early stages of the disease.
 Q. *(interrupting)*—Does the advertisement make any qualifications as to the stage of the disease?
 A. Not that I can find.
 Q. Have you ever seen that advertisement before?
 A. Not to my knowledge.
 Q. Who wrote it?
 A. *(By President Richardson)*—I done that ad, myself.
 Q.—Mr. Richardson, will Ozomulsion cure consumption?
 A. Sure; we got testimonials to prove it.
 Q. Have you ever investigated any of these testimonials?
 A. No.
 Q. *(By Dr. Smith)*—Dr. Smith, in view of the direct statement of your advertising, do you believe that Ozomulsion will cure consumption?
 A. Well, I believe in a great many cases it will.

Health for Five Dollars.

Dr. Slocum puts out a "Special Cure Offer" that will snatch you from the jaws of death, on the blanket plan, for \$5, and guarantees the cure (or more medicine) for \$10. His scheme is so noble and broadminded that I can not refrain from detailing it. For \$5 you get:

- 1 large bottle of Psychine.
- 1 large bottle of Ozomulsion.
- 1 large bottle of Coltsfoot Expectoant.
- 1 large tube of Ozogel.
- 3 boxes of Lazy Liver Pills.
- 3 Hot X-ray Porous Plasters.

"Which," says the certificate, "will in a majority of cases effect a permanent cure of the malady from which the invalid is now suffering." Whatever ails you—that's what Dr. T. A. Slocum cures. For \$10 you get almost twice the amount, plus the guarantee. Surely, there is little left on earth, unless Dr. Slocum should issue a \$15 offer, to include funeral expenses and a tombstone.

The Slocum Consumption Cure proper consists of a gay-buied substance known as "Psychine." Psychine is about 16 per cent. alcohol and has a dash of strychnin to give the patient his money's worth. Its alluring color is derived from cochineal. It is "an infallible and unfailing remedy for consumption." Ozomulsion is also a sure cure, if the literature is to be believed. To cure one's self twice of the same disease savors of reckless extravagance, and as "a perfect and permanent cure will be the inevitable consequence," perhaps it's worth the money. It would not do to charge Dr. T. A. Slocum with fraud, because he is, I suppose, as dead as Lydia E. Pinkham; but Mr. A. Frank Richardson is very much alive, and I trust it will be no surprise to him to see here stated that his Ozomulsion makes claims that it can not support, that his Psychine is considerably worse, that his special cure offer is a bit of shameless quackery and that his whole Slocum Consumption Cure is a fake and a fraud so ludicrous that its continued existence is a brilliant commentary on human credulousness.

Peruna, Lipozone, Duffy's Malt Whiskey, Pierce's Golden Medical Discovery and the other "blanket" cures include tuberculosis in their lists, claiming great numbers of well-authenticated cures. From the imposing book published by the R. V. Pierce Company of Buffalo I took a number of testimonials for investigation; not a large number, for I found the consumption testimonials rather scarce. From fifteen letters I got results in nine cases. Seven of the letters were returned to me marked "unclaimed," of which one was marked "Name not in the directory," another "No such postoffice in the state," and a third "Deceased." The eighth man wrote that the Golden Medical Discovery had cured his cough and blood-spitting, adding: "It is the best lung medicine I ever used for lung trouble." The last man said he took twenty-five bottles and was cured! Two out of nine seems to me a suspiciously small percentage of traceable recoveries. Much stress has been laid by the Proprietary Association of America, through its press committee, on the suit brought by R. V. Pierce against the *Ladies' Home Journal*, the implication being (although the suit has not yet been tried) that a reckless faker of a noble and worthy business has been suitably punished. In the full appreciation of Dr. Pierce's attitude in the matter of libel, I wish to state that in so far as its claim of curing consumption is concerned his Golden Medical Discovery is an unqualified fraud.

One might suppose that the quacks would stop short of trying to deceive the medical profession in this matter, yet the "consumption cure" may be found disporting itself in the pages of the medical journals. For instance, I find this advertisement in several professional magazines:

"McArthur's Syrup of Hypophosphites has proved itself, time and time again, to be positively beneficial in this condition [tuberculosis] in the hands of prominent observers, clinicians, and, what is more, practicing physicians, hundreds of whom have written their admiring encomiums in its behalf, and it is the enthusiastic conviction of many that its effect is truly specific."

Which, translated into lay terms, means that the syrup will cure consumption. I find also in the medical press "a sure cure for drapery," fortified with a picture worthy of Swamp-Root or Lydia Pinkham. Both of these are frauds in attempting to foster the idea that they will cure the diseases, and they are none the less fraudulent for being advertised to the medical profession instead of to the laity.

Consumption is not the only incurable disease in which there are good pickings for the birds of prey. In a recent issue of the *New York Sunday American Journal* I find three cancer epilepsy cures and a "cure of paralysis cured." . . . As space lacks to consider individually the nature of each nostrum separately, I list briefly, for the protection of those who read, a number of the more conspicuous swindles of this kind now being foisted on the public:

- Rupert Wells' Radiatized Fluid, for cancer.
- Miles' Heart Disease Cure.
- Miles' Grand Dropsy Cure.
- Dr. Tucker's Epilepsy Cure.
- Dr. Grant's Epilepsy Cure.
- W. H. May's Epilepsy Cure.
- Dr. Kline's Epilepsy Cure.
- Dr. W. O. Bye's Cancer Cure.
- Mason's Cancer Cure.

Dr. Williams' Pink Pills for Pale People, which are advertised to cure paralysis and are a compound of green vitriol, starch and sugar.

Purchasers of these nostrums not only waste their money, but in many cases they throw away their only chance by delaying proper treatment until it is too late.

Properly, a "cure" known as Bioplasm belongs in this list, but so ingenious are its methods that it deserves some special attention. In some of the New York papers a brief advertisement reading as follows occupies a conspicuous position:

"After suffering for ten years the torture that only an ataxic can know, Mr. E. P. Burnham of Delmar, N. Y., has been relieved of all pain and restored to health and strength, and the ability to resume his usual pursuits, by an easily obtained and inexpensive treatment which any druggist can furnish. To any fellow-sufferer who mails him a self-addressed envelope, Mr. Burnham sends free this prescription which cured him."—*Adm.*

Now, people who give away something for nothing and spend money advertising for a chance to do it are as rare in the patent medicine business as out of it, and Delmar, N. Y., is not included in any map of Altruria that I have learned of. E. P. Burnham, therefore, seemed worth writing to. The answer came back, promptly inclosing the prescription and explaining the advertiser's purpose:

"My only motive in the notice which caught your attention is to help other sufferers. You owe me nothing. I have nothing to sell. When you are benefited, however, if you feel disposed and able to send me a contribution to assist me in making this great boon to our fellow-sufferers better known, it will be thankfully received and used for that purpose."

I fear that Mr. Burnham doesn't make much money out of grateful correspondents who were cured of locomotor ataxia by his prescription, because locomotor ataxia is absolutely and hopelessly incurable. Where Mr. Burnham gets his reward, I fancy, is from the Bioplasm Company of 100 William street, New York, whose patent medicine he prescribed for me. I should like to believe that his "only motive is to help other sufferers," but as I find, on investigation, that the advertising agents who handle the "Burnham" account are the Bioplasm Company's agents, I am regretfully compelled to believe that Mr. Burnham, instead of being of the tribe of the good Samaritans, is probably an immediate relative of Ananias. The Bioplasm Company also proposes to cure consumption, and is worthy of a conspicuous place in the Fraud's Gallery of nostrums.

There are being exploited in this country to-day more than 100 cures for diseases that are absolutely beyond the reach of drugs. They are owned by men who know them to be swindles, and who in private conversation will almost always evade the direct statement that their nostrums will "cure" consumption, epilepsy, heart disease and ailments of that nature. Many of them "guarantee" their remedies. They will return your money if you aren't satisfied. And they can afford to. They take the lightest of risks. The real risk is all on the other side. It is their few pennies per bottle against your life. Were the facile patter by which they lure to the bargain a menace to the pocketbook alone, one might regard them only as ordinary followers of light finance, might imagine them fleching their gain with the confidential, half-brazen, half-asmled leer of the thimbleigger. But the matter goes further and deeper. Every man who trades in this market, whether he pockets the profits of the maker, the purveyor or the advertiser, takes toll of blood. He may not deceive himself here, for here the patent medicine business is nakedest, most cold-hearted. Relentless greed sets the trap and death is partner in the enterprise.—*Extract from Collier's Weekly*, Jan. 13, 1906.

Correspondence

Is Cancer Contagious?

MONTREAL, CANADA, Jan. 10, 1905.

To the Editor:—For more than ten years I have been convinced that cancer is a contagious disease, the cause of the contagion being either a cell or a microbe contained in the discharges. I am now gathering facts to prove that it is not hereditary, as most people believe. One of the facts which has become very apparent from the study of my cases is that it is the exception for a cancer patient to have had a father or mother who has died from cancer; while quite a number of them had come in contact with cancer patients who were not related to them and from whom I believe they contracted the disease. I would like to hear from any of your readers who have made similar observations. It would also be very interesting to know if there is any village, among the inhabitants of which no cases of cancer had ever occurred, until some one had imported the disease from another place, after which it has spread to others in the village. Any one sending me facts bearing on these two important points will receive due credit in the article which I am preparing for the meeting of the British Medical Association in Toronto this year. I recently published an article declaring that cancer was becoming very rare in my public and private practice, which I attributed to the fact that every woman with a lacerated cervix in the practice of myself and friends, had had the injury repaired or the cervix amputated so as to remove the scar tissue on which cancer grows best. Since then I have received a letter from a prominent gynecologist of Boston saying that this has been his experience also. Not only that, but I believe that a woman suffering from cancer of the uterus may, during a year or two before she dies, infect her friends and neighbors with cancer of the face, lips, throat, stomach and intestine. If this is so, it is important to make it known so that there may be a crusade for stamping out cancer by early operation, or when too late for that, then by isolation and disinfection. I am sure that no more important subject could occupy your pages than the investigation of the origin and spread of this terrible disease.

A. LAPHORN SMITH.

Queries and Minor Notes

SACCHARASCOPE ESTIMATION OF SUGAR IN URINE.

To the Editor:—1. Can you give me in full the method employed with the saccharascope (Nelson Baker & Co.)?

2. Is it an accurate means of estimating sugar in the urine? How does it compare in accuracy with the saccharometer (Einhorn's)?

3. What are the definite amounts of the reagents used with Ruhemann's uricometer?

G. K.

ANSWER.—The saccharascope of Nelson Baker & Co. consists of two chambers or receivers, one to contain the fermenting solution, the other to collect and measure the gas evolved in the fermentation. The fermenting chamber is filled to the mark with the urine, which is previously mixed with 15 grains of compressed yeast. A compensation tablet is then added, which will evolve just enough carbonic acid to saturate the liquid so that all the gas collected will represent sugar present in the urine. The measuring chamber is filled with water on which floats a layer of oil to prevent absorption of the gas, the upper surface of the oil being brought exactly to the zero mark. Insert the stoppers securely and set the instrument aside in a place where the temperature will be constantly 80 F., providing a container to receive the water which flows from the outlet tube as the fermentation proceeds. Allow the instrument to stand for 24 hours, and then read off the volume of gas collected, which will indicate directly the proportion of sugar present. If the preliminary examination has indicated more than three grains of sugar to the ounce, the urine will have to be diluted accordingly. The amount of urine used in this test is one ounce, and the amount of sugar indicated is grains per fluid ounce.

2. This method is as accurate as any such method can be, and depends on the accuracy of the calibration of the measuring chamber. If properly manipulated it should give a little more accurate results than Einhorn's method, but either are sufficiently accurate for clinical purposes.

3. The method and amounts of reagents used in the Ruhemann's uricometer are as follows: The test is based on the principle that a brown iodine solution is decolorized by a certain proportion of uric acid. Fill the dry glass tube to the lowest mark (85) with carbon bisulphide. A solution consisting of 15 grains iodine, 15 grains potassium iodide, 15 grains absolute alcohol and 185 grains distilled water is added up to mark 1. Add urine to mark 2.45 (2.6 c.c.). Close the tube with glass stopper and shake well; the CS_2 becomes of a dark copper brown color. Add more urine under continued shaking, and the CS_2 will absorb all free iodine and the mixture will appear like urine. Slowly adding more urine will change the yellow foam into white foam. After a while the color of CS_2 will turn pink. Keep adding urine and shaking until only a slight reddish coloration of CS_2 remains. Now shake vigorously and the CS_2 will turn porcelain white and the urine will look like whey. The test is finished when the indicator appears snow white, showing that all the iodine has been decolorized by the uric acid. Read off the proportion of uric acid at the surface of the fluid as parts per M. For this test the urine must be slightly acid.

INTERNATIONAL SURGICAL AND MEDICAL CONGRESSES

GOVERNORS HARBOR, BAHAMAS, Dec. 27, 1905.

To the Editor:—I would like to attend the International Surgical Congress to take place next spring in (I believe) Madrid, Spain. Would you kindly inform me who the secretary is and how I may become a member?

E. L. GROSSMAN, M.D.

ANSWER.—The next International Surgical Congress is to be held at Brussels in 1908. Further particulars will be found in THE JOURNAL, Oct. 14, 1905, page 1418. Since our correspondent speaks of the congress as to take place next spring in Madrid, he probably means the International Medical Congress. By referring to the index to the last volume of THE JOURNAL, Dec. 30, 1905, page 2055, we find that the International Medical Congress was mentioned on pages 337, 532, 1010 and 1582. The program is given on page 337, July 29, 1905. The secretary of the American Committee is Dr. Ramon Gutierrez, 75 W. 55th St., New York. In volume XLIV of THE JOURNAL, January to June, 1905, the International Medical Congress (according to the index on page 2033 of June 24, 1905) is mentioned on pages 159, 883, 1046, 1129, 1140, 1941 and 1942. On the two pages last mentioned are given the details of membership.

Marriages

JOHN W. BOLTON, M.D., Iola, Kan., at Kansas City, Mo., January 3.

CRAIG BARROWS, M.D., to Miss Elfrieda De Reene, both of Savannah, Ga., January 3.

ALFRED P. HOLZ, M.D., to Miss Minnie D. Droege, both of Seymour, Wis., December 27.

LEWIS BERLIN, M.D., Norfolk, Va., to Miss Pauline Yaffee of Philadelphia, January 14.

JOHN P. MULREXAN, M.D., to Miss Mary Carroll Byrne, both of Philadelphia, January 10.

BENJAMIN F. CORVIN, M.D., to Miss Ada H. Pettit, both of Brooklyn, N. Y., January 5.

FRANK W. FLEISCHAKER, M.D., to Miss Edna F. Levy, both of Louisville, Ky., January 10.

EDWIN R. KEEN, M.D., Caliente, Nev., to Miss Cora V. Achenback of Ogden, Utah, recently.

JOHN ROSS SIMPSON, M.D., to Miss Alma Filipe Parratt, both of Atlanta, Ga., January 2.

EDWARD T. ALFORD, M.D., Chicago, to Miss Bess Williston of Manchester, Iowa, January 17.

E. MARVIN DIBBLE, M.D., Marine, S. C., to Miss Allen Nebb of Greenwood, S. C., December 28.

JOHN M. GARRINGER, M.D., Oelwein, Iowa, to Miss May McCoil of Boonville, Ind., January 1.

CHARLES H. C. MILLS, M.D., Charlotte, N. C., to Miss Eliza Lamb of Williamson, N. C., January 9.

CHARLES F. GLADWING, M.D., Folsom, Cal., to Miss Harry Heywood of Berkeley, Cal., January 1.

EDWARD H. CLAUD, M.D., Portsmouth, Va., to Miss Daisy Camilla Nash of Norfolk, Va., January 16.

TAYLOR EDWIN DARRY M.D., Ancon, Canal Zone, to Miss Helen Story, at Barnesville, Md., January 11.

Deaths

Benjamin Walter Taylor, M.D. Medical College of the State of South Carolina, Charleston, 1858; a member of the American Medical Association; surgeon of the Second South Carolina Cavalry, C. S. A., and later medical director of the cavalry corps of the Army of Northern Virginia, with the rank of colonel; vice-president and president of the South Carolina Medical Association; three times president of the Columbia Medical Society; once president of the State Board of Health; delegate to the International Medical Congress at Philadelphia in 1876; a member of the Southern Surgical and Gynecological Association; visiting physician to the Columbia Hospital and to the South Carolina College Infirmary; a member of the board of regents of the State Hospital for the Insane, Columbia, since 1878, and for several years president of the board; one of the oldest and most distinguished practitioners of the state, died at his home in Columbia, December 27, from pneumonia, after an illness of six days, aged 71.

James W. Holland, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1894; a member of the American Medical Association; assistant medical examiner of the West Hampden district of Massachusetts; for two years an acting assistant surgeon in the Army, and on duty in the Philippine Islands; a member of the board of health of Westfield; a member of the staff of Noble Hospital; a member of the Massachusetts Medical Society, of the Hampden District Medical Society, of the Massachusetts Medical Society, and of the Association of Military Surgeons of the United States, died at his home in Westfield December 29, from nephritis, after a short illness, aged 37.

James Lang Harriman, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1857; a member of the American Medical Association, Massachusetts Medical Society, Middlesex South District Medical Society and White Mountain Medical Society; assistant surgeon of the Thirteenth Massachusetts Volunteer Infantry in the Civil War; once a member of the legislature; for 37 years member or chairman of the Hudson school board; the oldest resident physician in Middlesex County, Mass., died at his home in Hudson, December 28, from nephritis, after an illness of nine weeks, aged 78.

Thomas Clifford Potter, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1871; a veteran of the Civil War; surgeon of the veteran corps of the First Infantry, N. G. Pa.; one of the founders of, and consulting physician to the Germantown Hospital; a member of the Philadelphia County Medical Society and a fellow of the College of Physicians of Philadelphia, died from heart disease, January 8, at his home in Germantown, Philadelphia, after an illness of several months, aged 57.

Theodore J. Bluthardt, M.D. Chicago Medical College of Chicago, 1861; assistant surgeon in the First Illinois Volunteer Cavalry during the Civil War; county physician of Cook County from 1866 to 1869 and from 1880 to 1888; a member of the board of county supervisors in 1869, and president of the board in 1870; in 1872 a member of the board of education and superintendent of compulsory education; United States consul at Barmen, Germany, died at his post in that city, January 15, aged 68.

Calvin Snook, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1869; local surgeon for the Burlington System; some-time president of the Southwestern Iowa Medical Association, and of the Tri-state Medical Society of Illinois, Iowa and Michigan; a member of the Iowa State Medical Society; a member of the school board and the city council of Fairfield, Iowa, who was found unconscious in his office, January 2, died at his home two days later, from cerebral hemorrhage, aged 57.

Emmet Cooper Dent, M.D. Bellevue Hospital Medical College, New York City, 1879; superintendent of the Manhattan State Hospital for the Insane, Ward's Island, and professor of nervous and mental diseases at the clinic of the New York Hospital of Physicians and Surgeons; member of the Medico-Psychological Society, New York Academy of Medicine, state and city medical societies, died suddenly of heart disease, January 12, aged 47.

Daniel Meigs Webb, M.D. Medical Institution of Yale College, New Haven, Conn., 1849; a member of the Connecticut Medical Society and the New Haven County Medical Association; for 56 years a practitioner of Madison, Conn., died at his home in that place, January 1, from senile debility, aged 83.

Harrison Hathaway, M.D. Miami Medical College, Cincinnati, 1870; a member of the American Medical Association; a veteran of the Civil War; for 10 years a member of the Toledo Public Library board; one of the most esteemed practitioners of East Toledo, was struck by a train while walking across a trestle and instantly killed, January 4, aged 64.

Thomas H. Nott, M.D. Long Island College Hospital, Brooklyn, N. Y., 1874; surgeon in the Confederate service during the Civil War; president of the Texas State Medical Association in 1886; ex-president of the Board of Medical Examiners for the Twenty-third and Twenty-fourth districts, died at his home in Goliad, Texas, December 29, from heart disease.

Karl O. Bendeke, M.D. Chicago Medical College, 1869; of Minneapolis, Minn.; a member of the American Medical Association; for the last 15 years a specialist in ophthalmology and otology; twice a member of the city council, died in St. Barnabas' Hospital, Minneapolis, January 5, a short time after an operation for disease of the kidney, aged 64.

Emil C. Brendel, M.D. University of Erlangen, Germany, 1853; for many years a practitioner of Springfield, Ill.; surgeon of the Eighty-second Illinois Volunteer Infantry in the Civil War; eminent as a scientist and entomologist, died at his home in Cedar Rapids, Iowa, January 6, after a long period of invalidism, aged 72.

David Thomas Jenkins, M.D. Western Pennsylvania Medical College, Pittsburg, 1897, Pittsburg; professor of orthopedics and assistant to the chair of nervous diseases in his alma mater; local surgeon for the Pennsylvania System, died at the West Penn Hospital, Pittsburg, December 21, from pneumonia, aged 41.

Joseph Warren Hancock, M.D. University of Buffalo (N. Y.) Medical Department, 1870; clerk of the Pierce County board in 1877; county judge in 1885 and 1889, and a member of the State Board of Health in 1894, died at his home in Ellsworth, Wis., December 28, after an illness of about four years, aged 57.

John Dorrance Parsons, M.D. New Orleans School of Medicine, 1861; assistant surgeon of Bass' regiment, and Twelfth Texas Cavalry, C. S. A.; a member of the legislature in 1882; for several years president of the Dallas County Medical Association, died at his home in Dallas, December 26, aged 66.

Oswald M. Justice, M.D. College of Medicine and Surgery of the University of Minnesota, Minneapolis, 1897; formerly of Elysian, Minn., and coroner of Le Sueur County; convicted of crime in California and sentenced to six years' imprisonment, committed suicide in his cell by strangulation recently.

Charles F. Allan, M.D.S., a member of the American Medical Association, and chairman of the Section on Stomatology, 1906; orderly sergeant during the Civil War; member of the American Dental Association, died January 11 at his home in Newburgh, N. Y., from cerebral hemorrhage, aged 62.

Robert W. Steger, M.D. Vanderbilt University Medical Department, Nashville, 1877, formerly of Chicago, and since September last a resident of New York City, died in Bellevue Hospital, from the effects of morphin and chloroform, taken with suicidal intent, January 10, aged 48.

Clifford L. Stewart, M.D. Detroit (Mich.) College of Medicine, 1892; a member of the Wayne County Medical Society and for four years milk inspector for the Detroit Board of Health, died at Grace Hospital in that city, December 25, after an illness of six weeks, aged 38.

Frederick H. Simmons, M.D. Harvard University Medical School, Boston, 1851; for several terms justice of the peace; once a member of the city council of Provo, Utah, died at his home in that city, from senile debility, December 15, after a decline of two years, aged 74.

George H. Germain, M.D. Rush Medical College, Chicago, 1894, of Ponca City, Okla., died at St. Francis Hospital, Wichita, Kan., January 3, from septicemia following a railway accident four days before in which his foot was crushed necessitating amputation.

George Hasty, M.D. Cincinnati, Ohio, 1860; founder of a medical college and a member of its faculty for many years; for 20 years a medical editor, died at his home in Indianapolis, December 23, after an illness of four weeks, from tuberculosis of the larynx, aged 70.

W. H. McClain, M.D. St. Louis College of Physicians and Surgeons, 1893, assistant physician at the West Virginia Hospital for the Insane, Weston, died at that institution, December 27, from acute gastritis, after an illness of two weeks, aged about 40.

H. P. Monthorne, M.D. Faculty of Paris, France, 1870; a member of the American Medical Association; a specialist in electrotherapeutics; major-surgeon in the French army during the Franco-German War, died at his home in Spokane, Wash., December 3, from nephritis, after an illness of three weeks, aged 57.

Usher D. McDowell, M.D. Ohio Medical College, Cincinnati, 1888, formerly medical inspector of the Colorado State Board of Health and police magistrate of Longmont, died at his home in that city, January 3, after a long illness from tuberculosis, aged 40.

William Edgar Hemphill, M.D. Baltimore Medical College, 1892; of Arden, N. C.; coroner of Buncombe County, died at the Clarence Barker Memorial Hospital, Baltimore, N. C., December 25, a day after an operation for appendicitis, aged 35.

Selwyn A. Russell, M.D. Albany (N. Y.) Medical College, 1877, died at his home in Poughkeepsie, January 11, from starvation due to experimentation on himself in accordance to one of his theories in regard to the influence of mind over matter.

Horace M. Nash, M.D. University of Vermont Medical Department, Burlington, 1876, of Worcester, a member of the Massachusetts Medical Society, died suddenly in the City Hospital, Worcester, December 24, from heart disease, aged 61.

William Ernest Maddox, M.D. Medical Department University of Texas, Galveston, 1895; for three years hospital steward, United States Army in the Philippine Islands; died in Hobart, Okla., December 29, from pneumonia, aged 31.

Abbie Custer Tyler, M.D. New England Female College, Boston, 1868, of Washington, D. C., a member of the Medical Association of the District of Columbia since 1893, died in Warren, Mass., January, from heart disease, aged 70.

Uriah H. McMullen, M.D. Jefferson Medical College, Philadelphia, 1898, a member of the American Medical Association, of Merrittstown, Pa., died at the Jefferson Medical College Hospital, Philadelphia, January 1, aged 33.

Daniel R. Hibbard, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1864, city supervisor of Sturgis, Mich., for several years, died at his home in that city, January 2, after a prolonged invalidism.

George H. Rheingans, M.D. Milwaukee Medical College, 1898, a member of the Washington County Medical Society, died at his home in South Germantown, Wis., January 7, after an illness of nearly two months, aged 39.

D. Heber Plank, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1867, a member of the Berks County Medical Association, died at his home in Morgantown, Pa., January 4, aged 63.

John F. Mulherin, M.D. Niagara University Medical Department, Buffalo, N. Y., 1888, of Syracuse, N. Y., died at St. Joseph's Hospital in that city, January 7, from diabetes, after an illness of one year, aged 39.

Milburn Hill Logan, M.D. San Francisco, 1881, of San Francisco, who had been under treatment at the Agnew State Hospital, escaped from his home in San Francisco, and died from exposure, December 26, aged 50.

Abraham Rosenthal, M.D. College of Physicians and Surgeons in the City of New York, 1890, died recently at his home in Farmington, N. M. He had been ill for several years with pulmonary tuberculosis.

Frank M. King, M.D. Cincinnati, 1892, of Damascus, Ohio, committed suicide by shooting himself in the head, while dependent on account of domestic trouble, at Alliance, Ohio, January 2, aged 45.

Mary A. Hayward, M.D. New York City, 1883, a practitioner for fifty years, died at the home of her daughter in Brooklyn, N. Y., January 3, from disease of the stomach, after an illness of a week, aged 77.

Clayton L. Hill, M.D. University of Buffalo (N. Y.) Medical Department, 1864, a surgeon during the Civil War, died suddenly at his home in Buffalo, December 25, from heart disease, aged 66.

John Nelson Bowers, M.D. Medical Department of Western Reserve University, Cleveland, Ohio, 1885, died at his home in Westfield, N. Y., January 7, after a long illness from nephritis, aged 48.

John Kane, M.D. College of Physicians and Surgeons of Ontario, Toronto, 1905, died at his home in Cornwall, Ont., December 7, from injuries received in a runaway accident, aged 31.

Jacob McDowell, M.D. (County License, 1897), for more than half a century a practitioner of Adams County, Ind., died at his home near Geneva, Ind., December 18, from senile debility, aged 77.

Oliver P. Askam, M.D. Kentucky School of Medicine, Louisville, 1884, died at his home in Mountain View, Cal., January 2, from disease of the liver, after an illness of three weeks, aged 42.

Alexander H. Cooke, M.D. New York University, New York City, 1846, once chief of staff at St. Joseph's Hospital, Chicago, died at his apartment in Chicago, January 8, aged 83.

Peter F. Bellinger, M.D. Bellevue Hospital Medical College, New York City, 1879, of Durango, Colo., died at Mercy Hospital in that city, January 5, after a short illness, aged 50.

Dryden Johnson, M.D. New York University, New York City, 1878, of Antonito, Colo., died at St. Joseph's Sanitarium, Albuquerque, N. M., January 7, from nephritis, aged 55.

George A. Martin, M.D. Pennsylvania, 1886, a veteran of the Civil War, died at his home in Boone, Iowa, January 7, from bronchitis, after an illness of two months, aged 64.

John Gordon Frierson, M.D. Vanderbilt University Medical Department, Nashville, Tenn., 1886, died at his home in Mount Pleasant, Tenn., January 5, from pneumonia, aged 41.

Richard Hodgson, M.D. New York, 1867, secretary and treasurer of the Society for Psychical Research, died suddenly in Boston, December 21, from heart disease.

William B. Stoner, M.D. Kentucky School of Medicine, Louisville, 1892, of Sunbury, Pa., died at Clifton Springs Sanitarium, N. Y., January 9, aged 60.

Dudley Robinson, M.D. Medical College of Alabama, Mobile, 1860, a Confederate veteran, died at his home in Robinson Springs, Ala., January 1, aged 66.

George H. Randle, M.D. University of Nashville Medical Department, 1856, died at his home in Waco, Texas, January 5, after a long illness, aged 69.

Abraham L. Lewis, M.D. New York University, New York City, 1897, died from starvation in his room in Brooklyn, N. Y., December 27, aged 33.

John R. Murray, M.D. Atlanta (Ga.) Medical College, 1895, of Hazen, Ark., died suddenly at De Vall's Bluff, Ark., December 27, from drug addiction.

G. S. Millikan, M.D. Joplin (Mo.) College of Physicians and Surgeons, 1883, died recently from dropsy at his home in Schell City, Mo., aged 55.

Alexius L. Middleton, M.D. University of Maryland School of Medicine, Baltimore, 1860, died in Prince George County, Md., January 8, aged 73.

Francis M. Hill, M.D. Examination, Iowa, died at his home in Persia, Iowa, January 1, after a short illness from neuralgia of the stomach, aged 61.

Curtis T. Hines, M.D. New Orleans School of Medicine, 1869, died at his home in West Monroe, La., January 5, after a short illness, aged 60.

Richard L. Kendall, M.D. Illinois, 1897, of Aurora, Ill., died from nephritis at San Diego, Cal., January 1, after a long illness, aged 33.

Joseph L. Davis, M.D. Starling Medical College, Columbus, Ohio, 1889, died at his home in Charleston, W. Va., December 29, aged 46.

William B. Kaiser, M.D. New York, 1897, died at his home in Hoboken, N. J., December 29, after a lingering illness, aged 31.

William C. Nelson, M.D. Kentucky School of Medicine, Louisville, 1859, died at his home in Salvisa, Ky., December 17, aged 68.

Harriet N. F. Cooke, M.D. New York, 1868, died from cerebral hemorrhage at her home in New York City, January 7, aged 75.

Thomas D. Goodwyn, M.D. Atlanta, 1884, a Confederate veteran, died at his home in Oakland, Ga., December 29, aged 64.

Alois Blank, M.D. St. Louis Medical College, 1869, died at his home in St. Louis, January 5, after a brief illness, aged 57.

Harry Munger, M.D. Ohio, 1892, died at his home in Carlisle, Ky., January 4, after a lingering illness, aged 48.

Stacy Jones, M.D. Pennsylvania, 1853, for 33 years a practitioner of Darby, Pa., died recently at Seattle, Wash.

Louis A. Melze, M.D. Pennsylvania, 1885, died at his home in Chicago, December 28, aged 55.

Richard Randolph, M.D. died at his home in Philadelphia, January 10, aged 83.

Association News

New Secretary of Section on Nervous and Mental Diseases.

Owing to the ill health of Dr. David I. Wolfstein, secretary of the Section on Nervous and Mental Diseases, the chairman has appointed Dr. T. H. Weisenburg of Philadelphia, as secretary for the ensuing year. Dr. Wolfstein will go abroad as soon as he is able to travel.

NATIONAL LEGISLATIVE COUNCIL.

Proceedings of the Meeting, held at Washington, D. C., Jan. 9-11, 1906.

Preliminary Meeting of the National Committee on Legislation.

The Committee on Legislation met at the New Willard Hotel, Washington, D. C., 10 a. m. There were present: Dr. William H. Welch (Maryland), Dr. W. L. Rodman (Pennsylvania), and the Chairman, Dr. Charles A. L. Reed (Ohio).

The various questions of legislation were taken up in the following order: (a) The Army Medical Reorganization Bill; (b) the Pure Food and Drug Bill; (c) the Question of a Department of Public Health; (d) National Incorporation of the American Medical Association; (e) District of Columbia bills.

The address of the Chairman, to be presented to the National Legislative Council, was then delivered and, after some changes, was adopted.

The committee then adjourned to attend the conference with the National Legislative Council, January 9-11.

CHARLES A. L. REED, Chairman,
WILLIAM L. RODMAN, Secretary.

Opening Session.

The National Legislative Council of the American Medical Association met at the New Willard Hotel, Washington, D. C., Jan. 9, 1906, at 1:19 p. m.

Charles A. L. Reed, Chairman of the National Legislative Committee, called the meeting to order. At his request C. S. Bacon of Illinois was appointed Secretary. The roll was called as follows:

Dr. I. H. Moore, Treadwell, Alaska.
Dr. W. H. Sanders, Montgomery, Alabama.
Dr. C. T. Drennon, Hot Springs, Arkansas.
Dr. Clarence E. Yount, Prescott, Arizona.
Dr. P. B. Carpenter, San Francisco, California.
Dr. Walter A. Jayne, Denver, Colorado.
Dr. Elias Pratt, Torrington, Connecticut.
Dr. Geo. N. Acker, District of Columbia.
Dr. J. D. Fernandez, Jacksonville, Florida.
Dr. F. M. Ridley, La Grange, Georgia.
Dr. L. P. McCall, Boise, Idaho.
Dr. A. E. Sterne, Indianapolis, Indiana.
Dr. B. E. Fortner, Vinita, Indian Territory.
Dr. C. S. Bacon, Chicago, Illinois.
Dr. S. Bailey, Mt. Airy, Iowa.
Dr. Geo. K. Purvis, Wichita, Kansas.
Dr. C. Z. Ande, Cecilian, Kentucky.
Dr. Wm. M. Perkins, New Orleans, Louisiana.
Dr. Byron F. Barker, St. Paul, Minnesota.
Dr. John S. Fulton, Baltimore, Maryland.
Dr. S. D. Presbrey, Taunton, Massachusetts.
Dr. Fleming Carrow, Detroit, Michigan.
Dr. Arthur Sweetser, St. Paul, Minnesota.
Dr. B. L. Cully, Jackson, Mississippi.
Dr. F. J. Lutz, Kansas City, Missouri.
Dr. T. J. Murray, Butte, Montana.
Dr. A. S. von Mandelslo, Ashland, Ohio.
Dr. Geo. H. Thoma, Reno, Nevada.
Dr. Geo. Cook, Concord, New Hampshire.
Dr. L. M. Halsey, Williamstown, New Jersey.
Dr. G. W. Harrison, Albuquerque, New Mexico.
Dr. E. Elliott Harris, New York City, New York.
Dr. J. Howell Waver, Waverly, North Carolina.
Dr. J. D. Taylor, Grand Forks, N. Dakota.
Dr. Chas. A. La Reed, Grand Rapids, Michigan.
Dr. C. S. Babcock, Norman, Oklahoma Territory.
Dr. Kenneth A. J. Macdonald, Portland, Oregon.
Dr. Henry Butler, Philadelphia, Pennsylvania.
Dr. T. E. Seaton, Providence, Rhode Island.
Dr. O. B. Mayers, Newberry, S. Carolina.
Dr. R. C. Warner, Mitchell, S. Dakota.
Dr. D. E. Nelson, Chattanooga, Tennessee.
Dr. J. T. Wilson, Shreveport, Louisiana.
Dr. Henry La Motte, Salt Lake City, Utah.
Dr. E. T. Brady, Abingdon, Virginia.
Dr. A. B. Blythe, Montpelier, Vermont.
Dr. E. L. Thoburn, Spokane, Washington.
Dr. W. W. Golden, Ellins, W. Virginia.
Dr. Carl E. Steinen, Milwaukee, Wisconsin.
Dr. L. Strider, Cheyenne, Wyoming.

(Surgeon-General Walter Wyman, U. S. P. H. and M.-H. Ser., Washington, D. C.
Dr. R. A. Marmion, U. S. Navy Medical Ser., Washington D. C.
(Surgeon-General R. M. O'Reilly, U. S. Army Medical Ser., Washington, D. C.
* Deceased.
† Present.

William H. Welch and William L. Rodman of the National Legislative Committee; George H. Simmons, Chicago, Editor of THE JOURNAL A. M. A.; H. L. E. Johnson, resident trustee, Washington, D. C., and H. W. Wiley, chief of bureau of chemistry, Agricultural Department, were also present.

Dr. Reed announced that the work of the committees would be laid out at this session and that the committees could report on the following day. He also stated that calls of courtesy would be made on the President of the United States and on heads of the departments, senators and representatives, who had identified themselves with medical legislation. He then addressed the council as follows:

Address of Dr. Charles A. L. Reed on National Medical Legislation.

Medical legislation already pending before Congress is of the utmost importance to the public welfare, while other measures that are in contemplation are calculated still further to promote the agencies of the government created for the conservation of the life and health of the public. Some of these measures have already been brought to the attention of the Legislative Council and, through that body, to the attention of the profession and the public; but, in view of the fact that these same measures are now pending before a new congress, and in view of the fact that the personnel of the Legislative Council has largely changed, the National Legislative Committee has deemed it wise to submit them anew for your consideration.

THE ARMY MEDICAL REORGANIZATION BILL.

The Army Medical Reorganization Bill, which was considered by the former Legislative Council and which has been made the subject of referendum, is one in which the interests of the American medical profession are actively and earnestly centered.

It is to be remembered that the Army was reorganized by the act of Feb. 2, 1901, at which time Congress ignored the recommendations of the Surgeon-General with reference to the reorganization of the Medical Department. This failure on the part of the Congress amounted to a distinct discrimination against the medical department, whose proportionate increase in numbers was much less than that of the army in general. The incidental increases that were given to the Medical Corps were all of lower grades, as a result of which the prospects of promotion of medical officers were much less than those of any other staff corps. The logical result of this unjust discrimination was, first, the resignation of many able men from the service, and, second, the failure of the Army Medical Corps to attract desirable applicants for the vacancies which rapidly increased in number. To correct these defects the present Surgeon-General, through the General Staff, recommended amendatory legislation, by which the number of medical officers should be increased from 320 to 450, exclusive of the Surgeon-General; that the length of service required to secure promotion from the grade of first lieutenant to that of captain be reduced from 5 to 3 years; that examination be provided to determine the fitness for promotion up to and including the grade of colonel, and, finally, that a medical reserve corps be established, to consist of medical men who shall have been examined and, when found fit, commissioned without pay for service as medical officers, with a rank of first lieutenant, but, in case of war or other emergencies, to be subject to call with compensation pertaining to that rank.

The passage of this bill was urged by both Secretary Root and his successor, Secretary Taft, and was further recommended in a special message by President Roosevelt. The increase in number of the Medical Corps they hold is not excessive, while the reduction in the time of service necessary for promotion from first lieutenant to captain simply places the Army Medical Corps in this particular on a footing of equality with the most justly organized medical corps of the Navy. The increase in number of medical officers of the higher grades was simply a restoration of the order of things that existed before 1901, and is another instance in which the Medical Corps of the Army seeks to be placed on a footing equal with that of the Navy. The provision for examination for promotion up to and including the grade of colonel is simply a rational method of applying a wholesome stimulus to the intellectual activity of the corps, while the creation of a reserve corps is intended to do away with the universally condemned

system of contract surgeons, on which the regular Medical Department has been forced to depend for expansion in the presence of war or other emergencies.

It would seem, indeed, that a recapitulation of these facts, coupled with the demonstration that the proposed improvement would cost far less than the relative profits realized, would be all that is necessary to secure the approval of the measure by Congress. As a matter of fact the bill did pass the Senate in the last Congress and was reported favorably from the House Military Committee, but was excluded from consideration in the pressure of business in the closing hours of the short session.

An attempt has been made by the opponents of the measure in Congress to show that the proposed Army Medical Corps will interfere with the employment of medical officers of volunteers in time of war. This is not contemplated by the terms of the proposed measure and would not result in the event of its enactment.

The essential meaning of the Medical Reserve Corps is to furnish the Surgeon-General a reasonable basis of supply for medical services for the regular establishment and to furnish medical men thus employed a respectable military rank. At present the contract surgeon is a mere hireling, with absolutely no official status and no official authority. Under the proposed law he would be accorded a military rank that would give him a definite footing and command for him somewhat of the respect that is due to the representatives of a learned profession—a respect which, I regret to say, is not accorded to the contract surgeon under the existing order of things.

It is hoped that you will see your way clear simply to reaffirm the action of the previous Legislative Council and emphatically to memorialize Congress, urging the passage of this obviously just and salutary measure.

THE PURE FOOD AND DRUG BILL.

The Pure Food and Drug Bill, with the provisions of which you are already familiar and which was made the subject of a referendum to the medical profession by the previous Legislative Council, and which by that means received the unanimous support of the medical profession as represented in over 2,000 county organizations, is again brought to your attention at this time simply to launch it anew on the current of agitation throughout the profession. The bill was introduced into the House by the Committee on Foreign and Interstate Commerce and was passed early in the Fifty-seventh Congress by the House of Representatives by a very large majority. There was, however, no call for the "ayes" and "noes," in so far as I remember. It was laid before the Senate and was approved by the Senate Committee on Manufactures, but was never seriously considered by the Senate at all.

In the Fifty-eighth Congress the bill passed the House of Representatives early in the session by a vote of 201 "ayes" to 69 "noes." This was a very full vote, since the bill excited a great deal of interest and was adopted after two days' debate. It was laid before the Senate, approved with some amendments by the Senate Committee on Manufactures, was placed on the calendar, and after the holidays was taken up and made unfinished business. Judge Swayne, however, and the statehood bill took practically all of the time of the Senate until, finally, everything was out of the way and the bill came up for consideration, when a motion was made to displace it and take up the bill in regard to restoring cadets expelled from the naval academy. This motion received a majority vote, and so the Senate failed finally to consider the bill. Of course, the motion to take up the case of the cadets was made for the purpose of killing the bill and this succeeded. There is no doubt that the bill would have passed the Senate by a great majority if it had once reached the point of a vote.

It is probably unnecessary for you again to make it the subject of a general referendum, as the petitions and correspondence previously sent to Senator Heyburn are being utilized before the present Congress. It is important, however, that the medical profession, and, for that matter, the public, should be informed of the character of the opposition which was aroused by the measure before the last Congress. This opposition was active, insistent, persistent and, judging from the results of the conference, was effective. An analysis of the proceedings in committee showed that the antagonism was derived from the manufacturers of blended and otherwise adulterated liquors, from the fabricators of foodless foods, from importers of foods and medicines so worthless as to be denied a market in Europe where they are made, from the makers and purveyors of worthless or dangerous and enslaving drugs—interests which, in the aggregate, and judged by the character of their business, could not go clean-handed into

any court of justice or command an honest footing before any legislative committee or any legislative body in the country.

The interest of the medical profession in this measure is aroused from the special and intimate knowledge possessed by physicians of the influence of impure food on the public health, but more particularly of the disastrous results arising from the dispensing of medicines, many of which fall below the pharmaceutical standard. As a matter of fact while the pharmacopoeia assumes to establish a certain standard of drugs there is at present no national law nor, so far as I am informed, any state law to enforce that standard. As a consequence manufacturing establishments, some of them enjoying a high-grade of commercial respectability, openly acknowledge that they manufacture pharmaceutical preparations of varying degrees of purity. They plead in extenuation that this is to meet the demands of the market. The better druggist—those enjoying a high-class trade—are presumed to dispense the purest of the preparations. Those located in middle-class localities take the second grade, while the lowest, or third grade, is sold to public health departments, hospitals and deaconess-nursing institutions and country drug stores, but more especially to country practitioners who dispense their own medicines. That there should be any but one grade, and that the highest grade of pharmaceutical preparations, is an idea so repugnant to every sense of honesty, decency and common humanity that the present situation becomes revolting. If, then, we go a step further and consider that class of copyrighted preparations that are dispensed by physicians—the so-called "professional proprietaries"—we discover that the trade interests are absolutely without other restraint than that which is presumed to come from the effects assumed or demonstrated of such medicaments on the patients to whom they are administered. In this class of remedies there is not even theoretically a pharmaceutical standard, save as it applies to the ingredients of compounds, and there is no law that will hold the manufacturers of such remedies to the standard which they assume to establish for themselves.

To meet this condition the American Medical Association has established a Council on Pharmacy and Chemistry, which is doing voluntarily in a purely advisory way what ought to be done by the national government—namely, analyzing and testing these preparations for the purpose of advising the medical profession, and, for that matter, the public, of their true character. It is obvious, however, that this movement, salutary as it is, can not be sufficiently far reaching to keep our interstate commerce from being loaded down with preparations, many of which are essentially fraudulent in character. Under these circumstances I feel that it is important that the council reaffirm its previous action, and by such means as it may select to express its high appreciation of the service which has already been rendered by Senator Heyburn, chairman of the Senate Committee on Manufactures, and by Mr. Heyburn, chairman of the House Committee on Interstate and Foreign Commerce, in endeavoring to secure the passage of these salutary laws.

NATIONAL INCORPORATION OF THE AMERICAN MEDICAL ASSOCIATION.

It will be remembered that, a few years ago, an agitation was started to secure a national charter for the American Medical Association, which was then and is now in operation under a charter issued by the state of Illinois. The reasons given for the proposed change were two, namely (1) that the Illinois charter made it necessary that all acts of the Association to be legal had to be either originally taken or subsequently ratified at a meeting held in that state; (2) that the Association was a national organization and ought, therefore, to have a national charter. A special committee was appointed in 1904 to procure the desired legislation by Congress. That committee at the Portland session filed a report of progress, from which it appears: (1) That a bill was framed providing for national incorporation with "power to transact business anywhere in the United States," and that, in spite of the fact that the subcommittee having it in charge held it to be unconstitutional, it was introduced and referred to the Committee on Judiciary; (2) that the Committee on Judiciary, holding with the subcommittee that the foregoing provision was unconstitutional, reported the bill back to the House so amended as to constitute the American Medical Association, "a body corporate and politic within the District of Columbia." (3) The original bill was introduced in the Senate, but was never reported from the Committee on Incorporation, to which it was referred. (4) The opinion of the Committee on Judiciary of the House that the original bill was unconstitutional was opposed by the opinion of a distinguished lawyer, who acted

as the adviser of the special committee and who had served as the chairman of that committee in a former congress. The report which was received and, after reference, adopted, contained the recommendation: "That the efforts to secure national incorporation of the American Medical Association be and are hereby continued and that the labors relating thereto become a part of the duty of the Committee on National Legislation and that these duties be no longer referred to a special committee appointed for that purpose."

On attempting the task thus imposed on it the National Legislative Committee finds itself embarrassed by the fact that the Trustees of the Association in their annual report, likewise presented at Portland, contained the following statement:

The Committee on National Incorporation presented to Congress a bill proposing to incorporate this Association with a national charter. The effort was futile. The bill was soon made to read in such a way as to limit its rights and privileges to the District of Columbia. If through Congress a charter can be obtained limited to the District of Columbia only in its rights and privileges, subject to change at any time as may be dictated by a partisan Congress, then it would be better to leave the matter of incorporation alone. The property interests of the Association in the state of Illinois have now become too great to abandon our charter of incorporation in that state. Where our property interests are, there we should be domiciled. A home corporation, as a rule, gets more rights and privileges than does a foreign one. This is a matter to be viewed from a business standpoint alone. A District of Columbia charter will be no better than an Illinois charter, and would have to be registered as a foreign charter in that state, as would be the case with a charter granted by any state in the Union.

The foregoing recommendations by the Trustees, on the formal adoption of their report, became as much the expression of the House of Delegates as was the adoption of the report of the special Committee on National Incorporation. It thus happens that the National Legislative Committee is unable, from the record, to determine the wishes of the House of Delegates touching this matter. The situation is, furthermore, confused by representations made by the trustees directly to the National Legislative Committee to the effect: (1) That our property is in Chicago; (2) that we can best protect it as an Illinois corporation; (3) that a District of Columbia charter would make us a corporation foreign to the state in which our property is located; (4) that the present charter permits the Association "to carry on its business and have the annual session in any state in the union"; (5) that the dissolution of the Association under the present charter and its reorganization under a District of Columbia charter would entail complications dangerous to the welfare of the Association. In the dilemma created by the conflicting expressions of opinion by the House of Delegates, increased by the doubtful constitutionality of a national charter (assuming that such a thing is possible), emphasized by the undesirability of a charter limited to the District of Columbia, and still further confused by the questionable necessity for any change at all, the National Legislative Committee respectfully submits to you as its counsellors and advisers, whether or not it would be better to refer the matter back to the House of Delegates for more specific instructions coupling the reference with the recommendation that the movement be abandoned.

Certain new measures of more than usual importance are already under consideration. Two of them, emanating from the Department of the Interior, are local to the District of Columbia.

AMENDMENT TO THE LUNACY LAWS OF THE DISTRICT OF COLUMBIA.

The laws relating to the commitment and care of the insane in the District of Columbia are in certain particulars not only strikingly defective, but strikingly primitive. Thus commitment by a lay jury only after inquisition conducted in open court as now practiced is neither scientific, just nor humane, either to the patient or to the patient's friends and relatives. To remedy this evil, for an evil it is, it would seem a law is demanded which shall establish in the District of Columbia, just as the majority of states have established, the office of examiners in lunacy and prescribe their qualifications and duties and which shall furthermore provide that inquisitions by such examiners on lunacy may be conducted in chambers. To make such a course mandatory might theoretically lead to serious abuse and consequently to protect the personal rights of those alleged to be insane they, their friends, relatives or legal custodians ought to have the right to demand, and the court ought to have the authority to direct that proceedings be conducted in open session, but always before disinterested experts competent to exercise the most enlightened judgment on mental states. There should be some provision, too, whereby persons skilled in handling the insane, men for men and

women for women, should be designated as official custodians to conduct insane patients from their homes to court and from court to the hospital.

I lay before you a copy of the lunacy laws of the District of Columbia, a résumé of the laws of the different states relating to the commitment of the insane, and finally, a copy of the bill by which it is proposed to remedy the serious defects to which I have alluded. You are urged to give this question, with which, as medical men you are already familiar, that studious attention which will enable you to formulate safe and practicable recommendations for the consideration of Congress.

A LAW REGULATING THE TREATMENT OF INEBRIATES IN THE DISTRICT OF COLUMBIA.

Your attention is called to the fact that the laws and practices of the District of Columbia relating to inebriates is, likewise, far from satisfactory. At present inebriates are committed by proceedings obviously based on the theory that they are insane—at least the fact that they, like the insane, are committed after inquisition by jury in open court to a hospital established and conducted for the insane bears, out this theory. This, of course, is fundamentally and scientifically wrong. But assuming that the implied classification of such patients as insane were justified by the facts, the failure to commit them for a long enough time to subject them to successful treatment places the whole proceeding at variance with public policy. Thus, these cases as soon as they are sober, demand to be dismissed, and if this is denied, institute *habeas corpus* proceedings, with the result that they make such an appearance of physical health and mental soundness that they secure their discharge. The inevitable result of such premature discharge, before the physical conditions have been so far restored that the will power and the moral sense can reassert themselves, is a relapse into former habits. The final consequence is that the whole system, extensive enough, has a tendency to perpetuate rather than to curb inebriety. It is, however, the obvious duty of Congress to protect these victims of disease and, as far as possible, restore them to health. To this end you are invited to consider the terms of a measure by which inebriates in the District of Columbia may voluntarily commit themselves, or may be committed by court for a definite period, having possibly a maximum limit of one year.

THE REGULATION OF MEDICAL PRACTICE IN THE GOVERNMENT RESERVATION OF HOT SPRINGS, ARK.

In the early days of the country when Hot Springs, Ark., first became famous for its waters there were no laws, state or national, governing the practice of medicine. As a consequence this Mecca of invalids speedily became infested with many mere adventurers who, without professional qualifications, preyed on the public in the guise of physicians. Their numbers so increased that the struggle for existence, coupled with the spirit of rapacity, forced them to resort to the most dishonorable methods to secure patronage until no patient could be sent to Hot Springs with any assurance that he would reach the reputable physician to whom he had been accredited by his home attendant. The able physicians of the place were unable to protect themselves against this outrage until the government finally took over the springs and immediately adjacent territory as a reservation and placed its administration under the Secretary of the Interior. This officer sought to correct the evils of medical practice by executive order, in which "touting," "drumming" or "steering" patients was prohibited and by which a competent board of medical examiners was appointed to pass on the qualifications of practitioners. The disreputable element resisted this order, with the result that the court set it aside, declaring that it was without warrant of law, but adding significantly that Congress might enact such a law.

The matter is now brought to your attention by the effort of the organized medical profession of Arkansas to procure such legislation from Congress. It is important, therefore, to determine whether it is desirable to secure an act prescribing detailed provisions governing the practice of medicine on this reservation, or whether it is better simply to enlarge the powers of the Secretary of the Interior in the premises. Either means may accomplish the purpose. But something ought to be done to insure protection to the large public that annually visits this, the greatest natural sanatorium in the western hemisphere.

You are urged, therefore, to make some specific recommendations before the conclusion of our present conference.

A DEPARTMENT OF PUBLIC HEALTH WITH REPRESENTATION IN THE CABINET.

A measure to increase the powers and scope of the Public Health and Marine-Hospital service, more particularly with reference to giving it control of all coast and frontier quarantine, is in course of preparation. This step is the result of the recent disastrous epidemic of yellow fever in New Orleans, an epidemic that occurred, in the first instance, by a lack of such powers by the national health service, and that was controlled and promptly stamped out, in the second instance, by the scientific ability and superb executive force of that same service. The step is, however, the immediate result of one of the most remarkable and impressive conferences ever held in this country—a conference participated in by the governors of practically all of our southern seaboard states and of the states contiguous to them. This conference, held in Chattanooga, Nov. 9, 1905, unanimously requested Congress to enact a law placing coast maritime and national frontier quarantine exclusively under the control of the national government and to make necessary appropriations for a systematic campaign against the mosquito pest. The legislatures of different states were petitioned to enact laws as nearly as possible in conformity with the national measure asked for. In the meantime the American Medical Association, in July, had commended Congress for enlarging the powers of the national health service and took the following action:

Resolved, That the American Medical Association recommends to Congress that said service be aided in every proper manner in the prosecution of its important duties and that in its efforts to protect and improve the public health it be strengthened in any manner to promote its efficiency and character as the national health organization.

We are now called on to give effective expression to the sentiment of the national profession as indicated in this resolution. In doing so, however, it is important to consider not only the actual powers vested and to be vested in the national health service, but to take into the account the status that that service is now accorded and the status that ought to be accorded to it in our general scheme of government. It is not now accorded even the dignity of a bureau in charge of a commissioner, but, instead, is a service anomalous in organization and made subordinate to a department of the government to which it bears no more logical relation than it does to practically every other department of government. As a matter of fact the public health problems of this country are of strictly fundamental importance and underlie success in agriculture, manufacture, commerce and every other branch of human activity. This was shown in Cuba, where successful military operations depended on the work of the sanitary corps; it was shown in New Orleans, where the commerce of a city and of a great section of the country was paralyzed pending the suppression of an epidemic; it was and is being exemplified by the brilliant achievements of Colonel Gorgas in the Isthmus of Panama, where the gigantic operations of engineering stands at rest until successful sanitation makes their successful prosecution possible. The administrative machinery necessary to make effective a national public health service is already large, diverse and far reaching; but it is not yet as comprehensive as will be necessary when that service has been expanded to meet the actual demands of the country. Many bureaus, laboratories and other agencies conservative of the public health now exist in other departments of the government and either work at cross-purposes or unnecessarily and at considerable expense duplicate the work of each other. It is perfectly manifest that agencies of such importance ought to be correlated in a single department and that interests of such paramount importance ought to be distinctly and specifically represented in the supreme executive council of the country. These facts give further force to the declared policy of the American Medical Association, that the medical profession ought not to be placed in positions of responsibility without executive authority, subordinate only to that of the chief executive to control and determine results. The logical application of this principle found expression at the session of our national body held in this city as long as fourteen years ago, when a resolution was adopted calling for the organization of a department of public health, with representation in the cabinet of the President.

This question is now in the hands of the Committee on Legislation and is submitted to this conference for counsel and advice. It is suggested that in approaching the problem of creating a department of public health certain cardinal principles ought to be observed. The movement ought to be evolutionary rather than revolutionary, care being taken to conserve and expand rather than to hamper or disturb existing agencies. The national health-conserving agencies now scattered

throughout the governmental departments ought to be gathered into a single department with reference to both economy and efficiency. The scope and power of the department consistently with the exercise of the police power reserved to the several states ought to be greatly increased, particularly with reference to coast and frontier quarantine and sanitary control of interstate commerce and of all streams and waters under national jurisdiction. Facilities for hygienic research already established should be expanded, and a policy, both educational and executive, of the widest reaching influence ought to be inaugurated. These are but a few desultory observations, but they culminate in one of great importance, namely, that the movement ought to be undertaken with deliberation, care being taken to draft a proper law, after which there should be no pause until a Department of Public Health becomes an accomplished fact.

Committees Appointed.

Dr. von Mansfelde moved that the subject matter of the chairman's address be divided up, distributing it to the different committees, and that the chairman and secretary help in the deliberations of the committees. Carried.

Dr. H. L. E. Johnson of Washington was then called on to present more in detail the matters referred to by the chairman concerning the subject of canteen legislation in the Army and also the bill for the relief of the widow of General Hammond.

Dr. Reed then announced committees as follows:

ARMY MEDICAL REORGANIZATION BILL: C. S. Bacon, S. Bailey, G. K. Purvis.
PURE FOOD AND DRUG BILL: A. S. von Mansfelde, J. S. Fulton, S. D. Presbrey.
DEPARTMENT OF PUBLIC HEALTH: J. T. Wilson, C. Z. Aude, G. E. Seaman.
REGULATION OF MEDICAL PRACTICE AT HOT SPRINGS: W. H. Sanders, C. T. Drennan, O. B. Mayer.
HAMMOND, CANTEEN AND DISTRICT OF COLUMBIA BILLS: G. N. Acker, J. F. Fulton.
NATIONAL INCORPORATION OF THE AMERICAN MEDICAL ASSOCIATION: W. H. Welch, J. F. Fulton.

Dr. von Mansfelde moved that Dr. Simmons, Secretary of the American Medical Association, be requested to serve on all committees.

The members were requested to meet at 9:30 Wednesday morning to make the calls of courtesy previously announced by the chairman. The session then adjourned to meet at 2 p. m. on Wednesday.

Second Session—Visits to Cabinet Officers and the President.

The members met promptly at 9:30 a. m., and proceeded to the War Department, where they were received by the Secretary of War, William H. Taft.

In the course of the interview that followed the Secretary of War emphasized the brilliant success and the continued importance of the sanitary administration on the Isthmus of Panama and invoked the assistance of the council and, through the council, that of the medical profession in maintaining the present scale of compensation paid to the sanitary department on the Isthmus. This schedule of salaries, he explained, was being antagonized in Congress. In his opinion the great value of the work being done by the sanitary corps justified the compensation that was now being paid. He spoke, furthermore, of the Army Medical Reorganization Bill and of the great importance of making it attractive to the highest grade of medical talent and of providing a reserve corps of competent men on whom the surgeon general could rely for expansion under emergencies, whether in war or peace.

The next visit was made to Mr. Hepburn, chairman of the House committee having in charge the Pure Food and Drug Bill known by his name. Mr. Hepburn explained to the committee many details of the campaign to secure the enactment of the bill, and dwelt in particular on the opposition that it had encountered.

Following the call on Mr. Hepburn the council went by invitation of the Secretary of War, Mr. Taft, to be present at the White House on the occasion of the presentation of a medal of honor to Captain James Robb Church of the Medical Corps for distinguished services in carrying wounded soldiers off the field in the midst of the battle of Las Guasimas.

Remarks of President Roosevelt.

At the conclusion of the ceremony the Secretary of War introduced the council to the President, who addressed them as follows:

I want to say just a word of greeting to you, and to ask your influence on behalf of the medical corps, not only of the army, but of the navy. There is not a more exacting profession; there is not a profession which makes greater demands on those following it, and which more entitles them to the gratitude of mankind than is the profession which is yours. The army surgeon has to combine the work of your profession with the work of the military men of the line. In saying that, I want to call your attention to two specific things: one that is now being done by the men of your profession, and one the need of men of your profession.

First, the thing that is being done: All the United States is the debtor to the medical men who have accomplished such remarkable work on the Isthmus of Panama. You hear very close talk about making the dirt fly in Panama. Before making the dirt fly it was necessary to get the microbes under; it was necessary to grapple with the mosquitoes; necessary to eradicate disease.

That has been done to perfection. We have had the foundation laid for that wonderful piece of constructive engineering work, to dig the giant canal. Too much praise can not be given to those who have done this work in Panama. So much for tribute to your compers.

You recollect the complaint about hygienic conditions during the war with Spain. Complaint was made that the troops were not properly treated, etc. The blame rested not on any man then in office, but on our people as a whole, who had declined, through their representatives, to make provision long in advance for meeting such a need.

The Japanese have given us a good lesson in this, as in many other particulars, by the way they handled their army in the recent war. One of the reasons why their medical department did well—the main reason—was the fact that they had an ample supply of doctors who had been practiced in time of peace in doing the duties they would have to do in war. And until we have provision for an ample corps of doctors in the army so that they can be practiced in time of peace we will not have prepared, as we ought to prepare, for the possibilities of war. Until we thus prepare we can make up our minds that we are ourselves responsible for any disaster that occurs to any army that the United States may raise in the future, not the man who may be at the head of the army at the time. That is utterly unjust; and the people themselves and the representatives of the people in public life who have failed to provide the necessary means in advance—they are responsible when disaster comes. That applies to the Medical Department, and it applies to every other branch of the military establishment just as much.

Third Session—Report on Army Medical Bill.

The council met promptly at 2 p. m. The report on the Army Medical Reorganization Bill was presented by Dr. C. S. Bacon as follows:

The subcommittee on Army Medical Bill recommends to the National Legislative Committee the adoption of the following propositions:

1. The American Medical Association, through its National Legislative Council, reaffirms its support of the bill "to increase the efficiency of the medical department of the United States Army," and desires to express its deep conviction of the importance of this bill for the welfare of the Army of the United States.

2. It desires to express its appreciation of the interest shown in the advocacy of this measure by President Roosevelt, ex-Secretary of War Root, Secretary of War Taft and Surgeon-General O'Reilly, and its thanks to the Senate for the passage of the bill in the fifty-eighth session of Congress.

3. It recommends to the National Legislative Committee that further work with the congressmen be left to the discretion of the legislative committee.

4. It recommends the adoption of the following address to the Committee on Military Affairs of the House of Representatives:

There is widespread interest in the bill "To Increase the Efficiency of the Medical Department of the United States Army." Many medical societies from all parts of the country have taken the initiative in recommending action similar to that proposed by the bill, while the unanimous endorsement of the action of the Legislative Committee of the American Medical Association by the entire body of the profession in nearly all the countries of the United States shows that the physicians of the entire country believe that the measure is important and necessary.

Many of our physicians are more or less familiar with the objects and provisions of the bill, and so far as we know there has been a unanimous approval of its chief features, namely, the elimination of contract surgeons from the Army, the establishment of a Medical Reserve Corps and the increase in the number of officers to encourage young physicians to enter the service of the Army.

Whether the bill drawn up two years ago by Surgeon-General O'Reilly is the best possible bill in all details we do not feel competent to judge, but his masterly presentation of the reasons for its various features in the memoranda which accompany the former bill inspires us with confidence that he understands the subject and knows what is wanted and that anyone who has the ability and will to do it can do it. One of the chief reasons for the bill is too modest in its requirements and that a thoroughly efficient service may require a larger force than is provided for. In particular the Medical Reserve Corps should be fostered with much care, and we hope that if any changes are made by the committee they will be in the line of increasing the efficiency of this corps.

Now why is there such a deep and general interest among physicians in this bill? This question would be a useless one if the committee of congress which is considering the measure was composed of physicians. As there are no members of the medical profession on the committee, however, it is probable that the point of view of the physicians is somewhat foreign to the committee and so considerable of the reasons for the bill are not understood. This erroneous ideas concerning the forces that may have influenced us.

The medical profession feels itself the natural protector of the health of the state. One important function of medicine has always been to prevent disease. In recent years this function has become to be more important than any other. The greatly increased interest in reports of boards of health and in vital statistics which show the causes of epidemics and of all other causes of sickness and death has done much to increase this interest.

Necessary provision to guard against unhealthy conditions and epidemics of disease are obligatory and failure in forest and sanitary measures are medical crimes. An epidemic of smallpox or cholera fever in the city is a disaster to the health of the city, and is shared by the whole medical profession of such a municipality. The public respect for the medical profession should fall if its public spirit and interest in the health of the community does not keep it awake and alert to exercise that interest with care and efficiency in guarding public danger.

In support of this proposition the history of the action of the medical profession in a number of communities could be cited. Unfortunately lack of organization of the profession in the past has made it impossible for it to exercise that interest with the right belongs to it. The recent remarkable growth of organization in the medical profession in the United States has led it to feel its responsibility much more deeply.

This inherent interest in public health caused the profession to be most deeply moved and humiliated by the events of the Spanish war. The terrible epidemics of typhoid, quite unnecessary and avoidable, now when we knew the cause of the disease and its modes of propagation, that led to the sacrifice of many lives and to the enormous expense of the war, and the ill-health, made a deep impression on the physicians of the country.

All knew that there had been some great mistakes that was responsible for these epidemics and one which should be discovered and remedied when found. When the Dodge Commission, appointed by President McKinley, reported that one of the principal defects under which the medical department labored was a lack of trained surgeons of the regular medical corps and recommended an increase in their number, attention was called to the fundamental need of a medical department of an army, viz., men trained in army sanitation and administrative detail. Civilian physicians, no matter how skilled in their own special field of work, can not at once take charge of the medical supervision of an army.

All know the proper selection and sanitary preparation of camp grounds with proper disposal of sewage and the prevention of infection of drinking water and food, as well as keeping track of patients by means of a system of records, are matters that require much preparation. Military medical practice is, indeed, a specialty, as much as any other medical specialty and a military specialist can not be created in a day or a month, any more than a great abdominal surgeon can be made in that time. In the emergency of war these specialists are of inestimable value.

When in the reorganization of the Army in 1901 the recommendation of the Dodge Commission was ignored, when the suggestions of the then Surgeon-General Sternberg were dismissed without a hearing and the Medical Department not only not increased but greatly reduced in efficiency, those who kept informed of the situation became very indignant at such a situation of the medical profession. As the knowledge of the situation has gradually been disseminated during the last four years and as the condition of the Army in respect to sanitation has been brought into comparison with that of other countries, and as the need of the Army for this condition is not remedied now after the need for it has been set forth so often by the General Staff of the Army, by the Secretary of War, the President of the United States and after it has been shown that there is no contradiction in the recommendation of the country favor such action it seems likely that the interest of the physicians of the country will grow until they will want to know why their views on so important a subject should not be more fully considered.

Those who oppose the bill make a variety of objections. Some of these are irrelevant; for example, it is said that the Army is already top-heavy, with the officers numbering one-sixteenth of the Army, as if too large a number of officers in other departments, if such an excess exists, was a reason for objecting to a proper number in the Medical Department. Also irrelevant is the petulant assertion that every Army Bill is simply one to increase the rank and pay of the officers. Aside from these there are about five objections that should be considered.

1. No change in the present law is necessary. The condition of the health of the Army is good, as shown by the annual report of the Secretary of War. Should war break out, the civilian physicians would become very inefficient at such a short notice. Contract surgeons are now employed. They have no certain authority even over the hospital corps. They are being constantly changed, they are not trained in their work, and much less officers, hospital corpsmen and medical assistants. The training of war corps of trained men is absolutely necessary properly to care for the sanitation of the Army.

2. The increase in the number of officers in the higher ranks is not necessary. Answer: The best quality of men can not be secured without adequate compensation. In the Army both rank and pay are regarded as compensations. The pay is not large enough to make up for a lower position. The pay, indeed, is determined by the rank. The restricting of the number of the higher prizes in the medical department as compared with those in other departments of the Army is unjust to the medical officers, as it is unjust to the medical profession.

3. The proposition to promote lieutenants in three years is not desirable. Answer: This is a detail best understood by the Surgeon-General, but in a general way the same answer can be given as to objection 2, namely, it is necessary as an inducement to obtain a medical corps of the proper quality and standing.

4. The plan of the reserve corps is not practicable, nor well thought out. Answer: What better plan can be proposed? Certainly not the contract system now in vogue, which every one condemns. The plan proposed is elastic and leaves much to development, and that is its good feature. It will probably and certainly lead to the organization of a fine body of men, who will keep informed of the essentials of the Army practice and who, through voluntary association will have a great influence in the improvement of the service. The Reserve Corps will not necessarily interfere with the medical corps of the national militia, but it will probably, have an important influence in developing and molding such a voluntary association will have a great influence in the improvement of the service. The Reserve Corps will not necessarily interfere with the medical corps of the national militia, but it will probably, have an important influence in developing and molding such a voluntary association will have a great influence in the improvement of the service. The Reserve Corps will not necessarily interfere with the medical corps of the national militia, but it will probably, have an important influence in developing and molding such a voluntary association will have a great influence in the improvement of the service.

5. The country is now spending more than it takes in. Under these conditions we can not increase the expense. Answer: The increase in expense will be but slight, because the change from the contract surgeon system will be a considerable saving. The change contemplated will require four years, and as the new members of the staff must spend some months in the Army Medical School, there will be practically no increase during the first year. When the change is completed in four years, the deficiency in income should have disappeared. The cost is truly very little, for the great saving it will secure in life and health.

C. S. BACON, Chairman.
S. BAILEY,
G. K. PERVIS.

Report on the Pure Food and Drug Bill.

The report of the Committee on Pure Food and Drug Bill was presented by Dr. A. S. von Mansfelde, chairman of the committee, as follows:

Your committee appointed to consider legislation for honest foods and pure drugs begs leave to report that it has considered the suggestions of the chairman and has examined in detail the provisions of the Heyburn and Heyburn bills and finds nothing in these bills which, in the opinion of the members of the committee, would injuriously affect any legitimate business concerned in the manufacture and sale of foods, liquors or drugs, and that the bill would afford adequate protection to honest manufacturers of and dealers in such products and security against imposition, fraud or danger to the buyer.

Finally, your committee respectfully recommends that this legislative council lend its influence to the passage of the Heyburn and Heyburn bills and ask the profession at large to second the endeavor.

A. S. VON MANSFELDE, Chairman.
SILAS B. PRESBREY,
JOHN S. FULTON.

Dr. von Mansfelde, chairman of the committee, submitted the further recommendation that, in submitting the report of the council relative to the pure food and drug bill, to the committee of Congress, said report be accompanied by the section of the address by the chairman, Dr. Reed, relating to this subject.

Dr. H. W. Wiley, chief of the bureau of chemistry, Department of Agriculture, was on motion invited to address the council on the general subject of pure food and drug legislation. At the conclusion of his remarks the report of the committee was unanimously adopted.

Report on Department of Public Health.

The Committee on Department of Public Health submitted its report in the form of a preamble and resolution as follows:

WHEREAS, The medical profession, at the Portland Session of the American Medical Association, had good reason for endorsing the excellent work done by the Public Health and Marine-Hospital Service during the preceding ten years, has now better reason for asking for an amplification of its powers in view of the valuable services rendered commerce and the most vital interests of this country during the recent epidemic of yellow fever in the south and realizing that the national public health service should be placed on an independent basis. Therefore be it

Resolved, That it is the sense of the American Medical Association that a Department of Public Health, with representation in the cabinet of the President ought to be established, such department to embrace an expansion of the present Public Health and Marine-Hospital Service, with the addition of other public health agencies now existing and in operation in other departments of the government, together with such additional agencies and functions as may best subserve the public welfare.

Resolved, That the National Committee on Legislation be and is hereby instructed to proceed at once with the preparation of a bill for this purpose to be presented to Congress at the earliest practicable date, if possible during the present session.

Resolved, That the Trustees of the Association be and are hereby requested to appropriate one thousand dollars (\$1,000.00), or so much of the same as may be required to defray the expenses of the Committee on Legislation in employing a competent constitutional lawyer to draft a bill for a department of public health contemplated by these proceedings.

J. T. WILSON, Chairman.
C. Z. AUDE,
G. E. SEAMAN.

This report was adopted.

Anti-Nostrum Crusade Supported.

The chairman, Dr. Reed, called the attention of the council to the fact that the agitation long carried on by the medical profession against patent and secret proprietary medicines, had at last been taken up by two powerful periodicals, namely, the *Ladies' Home Journal* and *Collier's Weekly*, with the result that popular interest had been aroused as never before in this important subject. He felt, therefore, that it was due not only to these periodicals, but to the general public, that the co-operation of the medical profession should be made active and effective along the lines which, now that popular co-operation had been reasonably secured, promised something definite in the way of results. A letter from Mr. Edward Bok relating to this subject was then read, after which the chairman said that he would take the liberty of offering from the chair the following preamble and resolutions, which were adopted:

WHEREAS, The American Medical Association has long maintained the position that all proprietary remedies prepared to and dispensed by the medical profession, to be entitled to confidence must carry their respective formula in all advertising matter, and,

WHEREAS, The same principle applies with even greater force in respect of drugs and medicines sold directly to the general public, therefore be it

Resolved, That the Committee on Legislation of the American Medical Association be and is hereby directed to bring the influence of the entire medical profession to bear in securing the enactment by the various state legislatures, of an act as nearly as possible uniform prescribing that all "patent" or "proprietary" medicines shall carry an exact formula of their contents plainly printed on each original package and make the contents conform to the formula.

Resolved, That the said committee memorialize Congress to enact a law which shall prescribe that all "patent" or "proprietary" medicines and all advertising matter relating to the same which shall fail to comply with the foregoing conditions shall be excluded from the United States mails and from interstate commerce.

Resolved, That the Committee on Legislation be and is hereby requested to take such other steps as it may deem necessary and expedient to limit the evil results arising from the consumption of drugs and remedies the contents of which are unknown.

Report of Committee on National Incorporation.

The committee to whom were referred the recommendations of the chairman of the Legislative Council concerning the question of national incorporation of the American Medical Association beg to report that they approve of these recommendations.

It seems to be practically certain, in view of the unsuccessful efforts of the special committee of the association to secure a truly national charter and of the weight of legal opinion, that the only form of charter which can be secured from Congress would be a District of Columbia charter, which would be no more national in character than the existing Illinois charter, and would offer no advantages over the latter; indeed, would be less beneficial, inasmuch as the property interests of the association are now located in the state granting the charter.

The committee, therefore, recommend that the Legislative Council advise the Legislative Committee to refer the question of a national charter back to the House of Delegates, with a statement which shall make clear the impracticability of securing a charter of a truly national character or any congressional charter which will be more advantageous to the association than a charter from the state where the property interests of the association are located.

WILLIAM H. WELCH, Chairman.
JOHN S. FULTON.

The report of the committee was unanimously adopted.

Report on Regulation of the Practice of Medicine at Hot Springs, Arkansas.

The committee to which was referred the consideration of the situation at Hot Springs, Ark., as respects the regulation of the practice of medicine, respectfully reports that the conditions existing are as follows:

Two jurisdictions exist side by side, one that of the general government over the grounds occupied by the springs, called the Reservation; the other that of the State of Arkansas over the surrounding territory, occupied by the municipality of Hot Springs.

The State of Arkansas has enacted a law regulating the practice of medicine in the state, which law, of course, applies to the city of Hot Springs. The United States Congress has authorized the Secretary of the Interior to establish rules regulating the privilege of using the waters, both of which are intended to prevent illegal practitioners of medicine from pursuing their vocation. The law of the state and the rules established by the Secretary of the Interior have both been assailed in the courts, the cases are now pending, decisions will sooner or later be reached in both cases, and in the event of the law of the state and the rules promulgated by the Secretary of the Interior being upheld all legislation necessary to suppress the evil will have been achieved.

The committee, therefore, recommends that the medical profession of the United States use its influence to uphold both the law and rules, and also recommends that a vote of thanks be extended to Secretary Hitchcock for the wise and vigorous position he has maintained in regard to this matter.

W. H. SANDERS, Chairman.
C. TRAVIS DRENNEN,
O. B. MAYER.

This report was adopted.

Report on Bill for the Relief of Mrs. William A. Hammond.

Your committee has carefully considered this bill (Senate 290), introduced by Mr. Elkins, entitled "A Bill to Amend the Act Approved March 15, 1878, Entitled 'An Act for the Relief of William A. Hammond, late Surgeon-General of the Army,'" and recommends its approval by Congress.

JOHN S. FULTON, Chairman.
GEORGE N. ACKER.

This report was also adopted.

Report on Bill to Restore the Canteen in the Army.

Your committee finds that the bill to restore the canteen in the army occurs as a House measure (H. R. 8433), introduced by Mr. Morrell, entitled "A Bill to Repeal Section Thirty-eight of 'An Act Entitled an Act to Increase the Efficiency of the Permanent Military Establishment of the United States,' Approved Feb. 2, 1901, and for Other Purposes," is in the following language:

WHEREAS, The Secretary of War has submitted a report on the operation of this law, which shows that its effect has been to increase drunkenness, disease, insubordination, and desertion, moral and physical degeneration; and

WHEREAS, The present Chief of Staff, in his report that all of the generals in the service except two, all of the ten colonels of the cavalry, all of the seven colonels of the artillery, all of the forty-nine colonels of the infantry save one, and five hundred and four out of five hundred and sixteen commanding officers of companies, batteries and troops, for one reason or another, are opposed to the law; and

WHEREAS, The testimony of 90 per centum of those who in command of posts have expressed a positive opinion is that the law has increased drunkenness, desertion, absence without leave, and trials by court martial; ninety-five per centum saying that the condition of health has deteriorated, and all agreeing that morality and discipline have been injuriously affected; and

WHEREAS, The present Chief of Staff, in his report for this year just published, calls attention to the reports of the division and department commanders, nearly all of whom agree as to the bad results which have followed the passage of the law: Now, therefore,

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That section thirty-eight of an Act entitled "An Act to increase the efficiency of the permanent military establishment of the United States," approved Feb. 2, 1901, be, and the same is hereby repealed.

Sec. 2. That this Act shall take effect from and after its passage.

For the reasons set forth in the preamble to the foregoing bill, the bill itself is recommended for passage.

JOHN S. FULTON, Chairman.
GEORGE N. ACKER.

This report was also adopted.

Report on Government Recognition of the Services of Dr.

James Carroll.

Dr. John S. Fulton, of Maryland, introduced the following:

WHEREAS, In the year of our Lord nineteen hundred, a Yellow Fever Commission was appointed by the Army of the United States to investigate the causes of yellow fever and to devise means for its eradication, the said Yellow Fever Commission consisting of Dr. Walter Reed, surgeon in the Army of the United States, Dr. James Carroll, Dr. Jesse Lazear and Dr. Aristides Agramonte, acting assistant surgeons in the Army of the United States; and

WHEREAS, The said Yellow Fever Commission, consisting of Dr. Walter Reed, Dr. James Carroll and Dr. Aristides Agramonte

(Dr. Jesse Lazear, deceased), did then and there determine the cause of yellow fever, and devise means for its prevention, by which means yellow fever was eradicated from Havana and Cuba, and thousands of lives have been saved in the United States and other parts of the Western Hemisphere; and

WHEREAS, Dr. Jesse Lazear, an acting assistant surgeon in the Army of the United States, did subject himself to the bite of an infected mosquito, from which bite Dr. Jesse Lazear suffered death; and

WHEREAS, Dr. James Carroll, an assistant surgeon in the Army of the United States, did subject himself to the bite of a mosquito infected with yellow fever, and suffered a grave and almost fatal attack of yellow fever, being the first attack ever experimentally produced; be it

Resolved, That the National Legislative Council of the American Medical Association expresses its appreciation of the valuable work accomplished by the Yellow Fever Commission in the interest of humanity, the material and bodily welfare of the people and of the Army of the United States, and of the heroism and devotion of the aforesaid Major Walter Reed (deceased), Dr. James Carroll, Dr. Aristides Agramonte and Dr. Jesse Lazear (deceased); and be it further

Resolved, That this Council commend to the Government of the United States adequate recognition of the gallant and meritorious services of the said Dr. James Carroll, the only surviving member in the Army of the United States of the said Yellow Fever Commission.

This report was unanimously adopted by a standing vote.

Report on Government Regulation of Indigent Consumptives.

Dr. J. T. Wilson of Texas presented the following preamble and resolutions, which were adopted:

WHEREAS, The wandering indigent consumptives who seek relief from change of climate, go from state to state, without friends and without means become a burden, filling poor-houses, hospitals, and cheap boarding-houses, but of greatest interest by being a menace to public health in scattering the germs of tuberculosis wherever they go; therefore be it

Resolved, That the Committee on National Legislation take the matter under advisement looking to the passage of a law by which these people should be placed under national control for the protection of the public.

Resolved, That this committee take further action in an effort to have the government establish institutions for the care and treatment of indigent consumptives and thus subserve a great humanitarian purpose.

Fourth Session—Visits to Government Offices.

The council met at the capital at 10 a. m., Thursday, January 11, and waited in a body on Hon. W. B. Heyburn, United States Senator from Idaho, to whom they expressed their high appreciation of his services in endeavoring to secure pure food and drug legislation for the country.

At 10:30 a. m. the council appeared before the House Committee on Military Affairs, consisting of:

REPUBLICANS.

1. Hull, John A. T., Chairman, 7th District, Des Moines, Iowa.
2. Ketcham, John H., 21st District, Dover Plains, N. Y.
3. Parker, R. W., 7th District, Newark, N. J.
4. Capron, A. B., 24th District, Milwaukee, R. I.
5. Primes, G. W., 15th District, Galesburg, Ill.
6. Holliday, E. S., 5th District, Brazil, Ind.
7. Young, H. O., 12th District, Ishpeming, Mich.
8. Patterson, R., 12th District, Ashland, Pa.
9. Kahn, Julius, 4th District, San Francisco, Cal.
10. Fletcher, Loren, 15th District, Minneapolis, Minn.
11. Dawes, B. G., 15th District, Marietta, Ohio.
12. Miller, James M., 4th District, Connell Grove, Kan.
- McGuire, B. S., Oklahoma Territory.

DEMOCRATS.

13. Suizer, William, 10th District, New York, N. Y.
14. Hays, James, 7th District, Madison, Va.
15. Sladon, James, 14th District, San Antonio, Texas.
16. Broussard, R. F., 3rd District, New Iberia, La.
17. Talhott, J. F., 2d District, Towson, Md.
18. Wiley, A. A., 2d District, Montgomery, Ala.

* New members of the committee.

The chairman, Dr. Reed, explained the mechanism by which the medical profession of the United States arrives at a consensus on public questions, and presented its verbal but unanimous petition for the passage of the Army Medical Reorganization Bill then before the House.

Dr. C. S. Bacon (Illinois) presented the formal report of the National Legislative Council.

Remarks were made by Drs. William H. Welch (Maryland), A. S. von Mansfelde (Nebraska), and G. E. Seaman (Wisconsin). After numerous questions had been asked by the members of the committee and answered by members of the council, the latter withdrew.

Visits of courtesy to the Secretary of Agriculture, Mr. Wilson, and to the Secretary of the Interior, Mr. Hitchcock, closed the session.

C. S. BACON, Secretary.

Approved,
CHARLES A. L. REED, Chairman.

State Boards of Registration

The Public Service

COMING EXAMINATIONS.

New York State Boards of Medical Examiners, Albany, January 30-February 2. Secretary, Charles E. Wheelock, Albany.

NEBRASKA State Board of Health, State House, Lincoln, February 7-8. Secretary, George H. Brash, Beatrice.

Personal.—Dr. E. L. Godfrey of Camden, Secretary of the State Board of Medical Examiners, who was granted leave of absence recently, has had an attack of appendicitis, but has been operated on successfully.

Reorganization of the Wisconsin Board.—Dr. A. P. Andrus was elected president, and Dr. J. V. Stevens, secretary, of the Board of Medical Examiners, taking the places of Dr. J. R. Currens and Dr. Filp Forscheck, the retiring president and secretary. Two new members have been appointed on the board, Dr. P. H. McGovern and Dr. M. A. Barndt, both of Milwaukee.

Wisconsin's New Law.—Dr. J. V. Stevens, secretary of the Wisconsin State Board of Medical Examiners, sends us a copy of the law recently enacted by the legislature of Wisconsin. It is given entire as follows:

A bill empowering and requiring the Wisconsin State Board of Medical Examiners to refuse to grant licenses or certificates of registration to persons guilty of immoral, dishonorable or unprofessional conduct, and empowering the courts to revoke and annul any license or certificate issued to any person guilty of immoral, dishonorable or unprofessional conduct or fraud or perjury in connection with obtaining such license or certificate, or through error.

SECTION 1. It is hereby made the duty of the Wisconsin State Board of Medical Examiners to refuse to license or grant a certificate of registration to any person guilty of immoral, dishonorable or unprofessional conduct. The effect of this act is hereby vested with jurisdiction and power to revoke and annul any license or certificate of registration which has been heretofore or which may be hereafter issued to any person to practice medicine or surgery or osteopathy in this state, who is guilty of immoral, dishonorable or unprofessional conduct, or who has procured such license or certificate of registration by fraud or perjury, or where the same was obtained through error. On a verified complaint in writing being made by any person, to the district attorney of any county, charging any person holding such license or certificate with having, in said county, been guilty of any immoral, dishonorable or unprofessional conduct, as defined in this act, or with having procured such license or certificate of registration by fraud or perjury or error, said district attorney shall commence and prosecute an action in the circuit court of said county, against the person so complained against, to revoke and annul such license or certificate of such person. Such action shall be commenced and prosecuted as a civil action in the name of the state of Wisconsin as plaintiff, and against such person complained against as defendant, and the rules of pleading, evidence and practice in civil actions in the circuit court shall be applicable thereto, and either party may appeal from the circuit court to the supreme court as in other civil actions. Either party in said action may demand a jury trial, and the defendant shall have the right to be represented by counsel, and the court may permit counsel to assist the district attorney in the prosecution of such action. The costs of such prosecution shall be paid by the county in which said action is brought. If, on the trial of such action, the court finds, or the jury returns a verdict in favor of the plaintiff, judgment shall be rendered revoking and annulling such license and certificate of the defendant, and the clerk of the circuit court shall forthwith cause a certified copy of such judgment to be sent to the Secretary of the Wisconsin State Board of Medical Examiners to be filed for record in the office of said Secretary. Any person whose license or certificate has been revoked under the provisions of this act, who shall thereafter practice, or offer or attempt to practice medicine, surgery or osteopathy in said state, or who shall be punished under Chapter 426 of the Laws of 1903, No person shall be excused or privileged from testifying fully under oath or producing evidence documentary or otherwise, in any action, proceeding or examination brought under the provisions of this act, but no person shall be prosecuted or subjected to any penalty for or on account of any transaction, matter or thing, concerning which such person may so testify or produce evidence, documentary or otherwise, except for perjury committed in giving such testimony. If the court before which the trial is had shall determine that the complaint made to the district attorney was wilful and malicious and without probable cause, it shall enter judgment against the person making such complaint for the costs of such action, and a contempt of the same may be enforced by execution against the body of such complainant as in tort actions.

Sec. 2. The words "immoral, dishonorable or unprofessional conduct" as used in Section 1 of this act are hereby declared to mean: First, procuring, aiding or abetting a criminal abortion; second, either in his own name or in the name of another person, firm, association or corporation, in any newspaper, pamphlet or other written or printed paper or document, in any obscene manner or in a manner derogatory to good morals, the advertisement of any medicine or any mess whereby the regular periods of women can be regulated or the menses re-established, if suppressed, or being employed by or in the service of any person, firm, association or corporation, as a third, the obtaining of any fee on the assurance that a manifestly incurable disease can be permanently cured; fourth, wilfully betraying a professional secret; fifth, indulging in the drug habit; sixth, conviction of any offense involving moral turpitude.

Sec. 3. This act shall take effect and be in force from and after its passage and publication.

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending January 13, 1906:

Allen, John H., asst.-surgeon, granted twenty days leave of absence.

Kilbourne, E. D., asst.-surgeon, left Army General Hospital, Presidio of San Francisco, Cal., on thirty days' leave of absence.

Huntington, P. H., asst.-surgeon, ordered, on arrival at San Francisco, Cal., to proceed at once to Fort Rosecrans, Cal., for station.

Barney, Charles N., asst.-surgeon, reports for treatment at General Hospital, Fort Bayard, N. M.

Thompson, George H., contract surgeon, relieved from duty in the Philippines Division, and ordered to sail February 15 from Manila, P. I., for San Francisco, Cal., there to receive further orders.

Waddell, Ralph W., dental surgeon, left Fort Mackenzie, Wyo., for duty at Fort Washakie, Wyo.

Mason, George L., dental surgeon, left Fort Fremont, S. C., and arrived at Fort Moultrie, S. C., for duty.

Whinnery, Jean C., dental surgeon, returned to Vancouver Barracks, Wash., from leave of absence.

Wolver, F. Homer, dental surgeon, returned to Fort McKinley, Maine, from leave of absence.

Carpenter, Alden, dental surgeon, left Vancouver Barracks, Wash., on leave of absence for one month.

Reltz, Hugo C., dental surgeon, left Fort Sheridan, Ill., on leave of absence for twelve days.

Newlove, George, contract surgeon, leave of absence extended fifteen days; at expiration of leave, proceed to New York City for duty as surgeon of the transport *McClellan* on its next voyage to Manila, P. I.

Kennedy, James S., contract surgeon, returned to Fort Omaha, Neb., from leave of absence.

Lowy, Abraham S., contract surgeon, sailed from San Francisco, Cal., for Manila, P. I., on the transport *Thomas*, after leave of absence in the United States.

Ivays, Caspar R., contract surgeon, returned from Fort McIntosh, Tex., to Fort station Fort Sam Houston, Tex.

Maey, Fred S., contract surgeon, ordered to accompany B. 9th Infantry, from Allegheny Arsenal, Pa., to Fort Porter, N. Y.; to accompany the 1st Infantry thence to New York City, and there report for further orders.

Dickenson, Clarence F., contract surgeon, relieved at Fort Logan, Colo., and directed to accompany the 2d Infantry to Philippine service.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending January 13:

Leach, P., surgeon, detached from the *Massachusetts*, when placed out of commission, and ordered to the *Indiana*.

Angwin, A. A., asst.-surgeon, detached from the *Massachusetts* when out of commission, and ordered to the *Indiana*.

Schebek, L. O., pharmacist, ordered to the Naval Hospital, Norfolk, Va.

Hindburn, T. C., acting asst.-surgeon, detached from the *Franklin*, ordered home, and granted leave until expiration of appointment as acting assistant surgeon, January 23.

Curts, E. E., acting asst.-surgeon, ordered to the *Franklin*.

McMurdy, P. F., acting asst.-surgeon, detached from the *Franklin*, ordered home, and granted leave until expiration of appointment as acting assistant surgeon, January 23.

Miller, J. T., acting asst.-surgeon, ordered to the *Franklin*, January 15.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending January 10:

Wasdin, Eugene, surgeon, leave of absence granted for one month from Dec. 15, 1905, amended so as to be effective from Dec. 17, 1905.

Carlington, P. M., surgeon, directed to proceed to El Paso, Tex., for special temporary duty.

Nydegger, J. A., P. A. surgeon, granted leave of absence for one day, January 2.

Sprague, E. P., P. A. surgeon, relieved from duty at Ellis Island, N. Y., and directed to proceed to Cape Fear Quarantine Station and assume command of the service.

Goldberger, Joseph, P. A. Surgeon, relieved from special temporary duty at New Orleans, and directed to rejoin his station in Washington.

Earle, B. H., P. A. surgeon, granted leave of absence for four months from February 4.

Shenck, E. E., asst.-surgeon, relieved from duty at Tampa Bay Quarantine and directed to proceed to San Francisco, Cal., and report to the medical officer in command for duty and assignment to quarters.

McKoon, E. H., asst.-surgeon, relieved from duty at New Orleans, La., and directed to proceed to San Francisco Quarantine Station, reporting to the medical officer in command for duty and assignment to quarters.

Spratt, R. E., asst.-surgeon, relieved from duty at Louisville, Ky., from temporary duty at Gulf quarantine Station, Miss., and directed to proceed to Mobile, Ala., assuming temporary charge of the service at that port.

Quinn, M. C., asst.-surgeon, relieved from duty at Cape Fear Quarantine Station, and directed to proceed to New York and report to Surgeon Stoner, Ellis Island, N. Y., for duty.

Bean, L. C., acting asst.-surgeon, granted leave of absence for two days from January 8.

BOARDS CONVENED.

Board convened to meet at Boston, Mass., for the physical examination of an Inspector in the Immigration Service. Detail for

the board: Surgeon R. M. Woodward, chairman; Acting Asst-Surgeon F. H. Clavess, recorder.
Board convened to meet in Philadelphia, Pa., Jan. 9, 1906, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon F. Irwin, chairman; Assistant Surgeon H. McEl Robertson, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended, January 12:

SMALLPOX—UNITED STATES.

District of Columbia: Washington, Dec. 31-Jan. 6, 4 cases.
Florida: Jacksonville, Dec. 31-Jan. 6, 6 cases; Mayo, 3 cases; Newberry, 2 cases.
Louisiana: New Orleans, Dec. 31-Jan. 6, 2 cases.
Maryland: Baltimore, Dec. 31-Jan. 6, 6 cases.
Missouri: St. Louis, Dec. 24-Jan. 6, 2 cases.
Virginia: Norfolk, Jan. 3, 35 cases (5 in city and 40 on Craney Island).
Wisconsin: Appleton, Dec. 31-Jan. 6, 3 cases.

SMALLPOX—FOREIGN.

Brazil: Bahia, Nov. 25-Dec. 9, 39 cases, 1 death; Rio de Janeiro, Nov. 20-Dec. 3, 15 cases, 11 deaths.
Ecuador: Guayaquil, Dec. 3-10, 2 deaths.
France: Paris, Dec. 16-23, 19 cases, 1 death.
India: Calcutta, Nov. 25-Dec. 3, 6 deaths; Karachi, Dec. 3-10, 1 case; Madras, Dec. 2-8, 3 deaths.
Italy: Messina, Dec. 9-16, 1 case.
Mexico: City of Mexico, Dec. 8-16, 4 cases, 2 deaths; Tuxpam, Dec. 26-Jan. 2, 2 deaths.
Russia: Odessa, Nov. 11-18, 19 cases, 1 death.
Turkey: Constantinople, Dec. 3-10, 3 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Nov. 20-Dec. 3, 4 cases, 2 deaths; Sao Paulo, Nov. 5-12, 1 death.
Columbia: Barranquilla, Nov. 27-Dec. 4, 6 cases, 4 deaths; Cartagena, Dec. 16-23, 1 case, 1 death.
Cuba: Habana, Jan. 1-4, 1 case, 1 death.
Ecuador: Guayaquil, Dec. 3-10, 4 cases.
Mexico: Merida, Dec. 24-30, 2 cases; Vera Cruz, 1 case, 1 death.

CHOLERA—FOREIGN.

India: Bombay, Dec. 5-12, 1 death; Calcutta, Nov. 25-Dec. 2, 1-2 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Nov. 29-Dec. 3, 42 cases, 18 deaths.
India: General, Nov. 4-11, 5,611 cases, 2,760 deaths; Bombay, Dec. 5-12, 15 deaths; Calcutta, Nov. 25-Dec. 2, 20 deaths; Karachi, Dec. 3-10, 5 cases, 5 deaths.
Russia: Government of Astrakhan, Nov. 19-Dec. 3, 680 cases, 651 deaths.

Medical Organization

What Can the County Society Do?

IV. CLINICAL MEETINGS.

Wherever they have been thoroughly tried, clinical meetings, as contrasted with meetings given over to the reading and discussion of essays, have proved both popular and instructive. Members will come out to see interesting cases when too tired to feel interested in any one's paper. Cases are always interesting, no matter how commonplace they seem, if they are well worked up and briefly and concisely presented. The methods of physical diagnosis are in this way tried and perfected, and the relative merits of different modes of treatment are discussed. If the county has a hospital an occasional meeting should be held in it and the cases used for study and demonstration.

V. BUSINESS MEETING.

If the society meets weekly or bi-monthly, there may profitably be one or two meetings a year given over to "business." This would include consideration of fees and collections, of drug store prescribing and substitution, expert testimony in court, consultations, contract practice, legislation, quackery, the hospital and dispensary evil, and, not least, methods of advancing the members and prestige of the organization.

VI. CONSULTATIONS.

Probably no one phase of professional life has given rise to more misunderstanding and bickering than the matter of consultations. Out of this little matter of conduct grew the great schism that some twenty years ago rent the American Medical Association, and only now is the breach at last closed by the reunion in New York. It is a rare village in the union where there is not or has not been a medical quarrel arising in a consultation. In nine cases out of ten the quarrel arose be-

cause the patient or his friends either deliberately or unwittingly placed a false construction on some remark of one of the consultants, but the doctors on that account disagreed none the less bitterly. One of the chief objects of a county society is to promote such a feeling of good-fellowship among the physicians that little gossiping misstatements will be smiled away in confident trust of a brother physician's honor. And so it is a wise plan at one or more meetings frankly and squarely to discuss consultations. The text of the discussion can be drawn from Article III of the "Principles of Ethics" of the American Medical Association, and the illustrations from the experience of every member. The discussion should be guided through this thorny subject in such a way as to give each member a clear idea of the best methods to be followed in calling and conducting consultations. The members can agree among themselves as to just what forms shall be adopted as necessary to the local circumstances.

(To be continued.)

Society Proceedings

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Dec. 27, 1905.

The president, DR. JAMES M. ANDERS, in the Chair.

The Nostrum Evil.

DR. ALBERT P. FRANCINE outlined the development of the reform against the nostrum evil which, he said, had reached the high water mark in the action of the American Medical Association in creating a Council on Pharmacy and Chemistry. He said that one hundred million dollars was spent by the public in a year in the purchase of patent medicines, of which forty million goes to the newspapers. Within the past year nine county medical societies have taken action and the crusade has been prosecuted vigorously by two notable lay journals, *Collier's Weekly* and the *Ladies' Home Journal*. He said that the medical journals, with a few gratifying exceptions, are as badly hoodwinked by the so-called ethical concerns as is the lay press by the quack nostrums. He instanced two government agencies as lending themselves to the purposes of the patent medicine venders. The Patent Office issues to them trademark registration without inquiring into the nature of the article thus safeguarded against imitation. The Postoffice Department permits them the use of the mails. He feels that the onus of the responsibility in the widespread use of these nostrums must rest, at least, indirectly with the medical profession.

With reference to the so-called ethical preparations, he said there is technically no difference between the proprietary medicines manufactured for the physicians' use and the patent medicines exploited to the public. In theory they reflect the advance made in pharmaceutical science; in fact, taking the greater number as criteria, they discredit pharmaceutical science. For the solution of the difficulty he made the following suggestions: There should be eliminated from the medical journals all advertisements of proprietary medicines of unknown formula, or those not sanctioned by the Council on Pharmacy and Chemistry of the American Medical Association. Physicians should never, under any circumstances, prescribe these mixtures or give testimonials. Medical schools should give their graduates a wider and more thorough knowledge of compounding and prescribing drugs. United action should be taken by medical organizations in the adoption of resolutions condemning this abuse, and in the appointment of committees to visit lay editors and publishers and urge on them the elimination of these advertisements from their columns. He believes that if the newspapers and lay journals could be brought to see the wrong they are committing by publishing advertisements of nostrums, legislation would become of secondary importance. Pending the awakening of the journalistic conscience, he believes legislation to be the most obvious remedy. State laws should be enacted to supplement the contemplated action of the federal government. He be-

lieves that the campaign of publicity and education should be vigorously carried forward so that the true nature and composition of these nostrums shall become public and common property.

The "Patent Medicine" and Secret Nostrum Evils.

DR. JAMES M. ANDERS read a paper which will appear in *THE JOURNAL*.

The Elimination of the Nostrum Traffic, an Evident Duty of American Physicians.

MR. M. I. WILBERT's paper on the above subject will appear in *THE JOURNAL*.

DISCUSSION.

DR. S. SOLIS COHEN spoke of the inauguration of the movement against the nostrum evil by the Philadelphia County Medical Society in 1892. These resolutions, Dr. Cohen said, had grown out of an experience of his own with a patient, the proprietor of a very influential newspaper in Philadelphia, who, when spoken to about his advertisements of nostrums, said: "Clean your own house, and then come to me." On further looking into the question, the same character of advertisements were found in several leading medical journals. Reference was made to the great improvement made in this respect in the pages of *THE JOURNAL* of the American Medical Association, and of the assurance that ultimately the work would be completed.

He thought a distinction should be made between "patent medicines" and "patented medicines," and instanced Lydia Pinkham's preparations as "patent medicines," but not "patented." Antipyrin was, but is no longer, a patented preparation, because the patent has expired. Antipyrin and phenacetin were mentioned as "patented" remedies which might with propriety be prescribed in suitable cases. "Patent medicines" he designated as purely nostrums, secret preparations advertised to the laity and for which unfounded curative virtues are claimed. The so-called "ethical proprietary" remedies are not ethical, because they are secret. The synthetic remedies are in an entirely different class, being of definite chemical composition which will respond to recognized tests for identity, quality and purity. These, he said, might be called "ethical remedies," but the so-called "ethical proprietaries" form another class. He thought there is a certain definite limited field for the class of proprietary remedies of known and definite composition, which are made up with peculiar pharmaceutical skill; that there is also a very definite place for the synthetic remedies of definite chemical composition subject to definite chemical tests for identity and purity. The patent medicines, however, and the secret remedies advertised to the profession no self-respecting physician can possibly use. He recognizes the power exercised by the money interests of the advertisements and that the principal fight must be with the power exercised over the medical press. If the members of the profession confine their subscriptions and articles to those journals which have perfectly clean columns, all the other medical journals will fall into line. He favors the passage of resolutions approving the stand taken by the president and officers of the American Medical Association, and offering a vote of thanks to the Council on Pharmacy and Chemistry and pledging the support of the society.

DR. ALFRED STENGEL agreed with Dr. Cohen in the idea of withholding subscriptions or articles from journals advertising such nostrums as are excluded from *THE JOURNAL* of the American Medical Association. He said that due credit should be given to Mr. Bok of the *Ladies' Home Journal* and to Mr. Adams of *Collier's Weekly* for having taken the initiative in this matter. He feels also that the profession should aid in this further exploitation through lay journals. He agreed that there are a certain number of proprietary preparations which owe their value to the efficiency of the chemist or to the method of preparation, and that this method of preparation can be patented, and the remedy will then become an entirely ethical proprietary remedy. The difficulty lies in deciding where the line should be drawn. Before such preparations can become ethical their exact formula should be printed.

Relative to secret remedies, he said there can be no question

where the profession should stand; how any one can prescribe for a sick person a remedy, the composition of which he does not know, is incomprehensible. He believes the cause of the extraordinary use of nostrums is largely the delinquency of the medical profession, shown in indifferent study and careless diagnosis; and that a greater respect for the profession of medicine as a scientific calling, a more decided attempt to ascertain the real cause of pathologic conditions, and a greater desire to be candid and honest when conditions are not solved, would insure a greater respect on the part of the public toward the profession and a tendency to accept medical judgment rather than to dose themselves with anything happening to fall under their notice. He felt that every physician in the country, certainly every member of the American Medical Association, should read the publications of the Council on Pharmacy and Chemistry when that Council shall have become operative. He believes that then physicians will give more consideration to the older remedies and not be so ready to take up with the new; also that the public will not be so prompt to use them without sanction from the medical profession.

MR. SAMUEL P. SAUTLER thought there should be the effort to distinguish between the relative standing of the so-called newer remedies. The United States Pharmaceutical Committee has approved about 18 or 20 of the newer synthetics, a relatively small percentage of the three or four hundred of the standard synthetics. He said that the Council on Pharmacy and Chemistry has much sifting work to do. Even among the compounds claimed to be definite, investigation has shown one preparation not to be what was designated by the patent, and he hopes that the Council will see fit to make this information public. The medical profession should continue its support of the American Medical Association and make possible the accomplishment of definite results.

DR. J. HENRICH LLOYD said that one of the obstacles to the proper control of the matter is the apathy of the members of the medical profession. He spoke especially with reference to proprietary medicines in their relation to medical journals and referred to his own experience as editor-in-chief of a medical journal in refusing advertisements of nostrums. He cited an instance of a paper brought to him for publication extolling the virtues of a certain lithia water, said to have been written by a professor in one of the Philadelphia medical colleges and for which the professor had been paid three hundred dollars. Dr. Lloyd thought it needless to state that the paper did not appear in the *Philadelphia Medical Journal*. Dr. Lloyd said that the fight against the nostrum evil should not be the fight of the medical profession alone, because more is involved than the interests of the profession; but as guardians of the people the medical profession owes a duty to the public. In his judgment, an opinion of a medical journal should not be based on the editorial columns. The reader should not be taken in by an editor who is shouting for ethics, but should look at the advertising pages to see whether they contain a lot of quack advertisements.

DR. M. C. TIRUSH said it is well known that if the formulae of the secret nostrums were published they would soon meet their Waterloo, and instanced a certain sulphur bitters advertised to contain no alcohol, when in reality it contains no sulphur and 20 per cent. of alcohol. Physicians should absolutely condemn the sale of such preparations and call the attention of the people to the great harm they are doing.

DR. IL. C. WOOD, JR., did not agree with Drs. Cohen and Stengel in placing the fault on the medical profession. The medical profession, he said, as a whole, does not know what these things are; no one but a trained pharmacologist can differentiate between patent medicines, the secret pharmaceutical, the synthetic, and the so-called synthetic preparations. The only way possible for the medical profession to know the truth is to have it set forth in medical journals, and this truth, he said, the medical journals will not publish. From actual personal knowledge of a large number of medical journals, only those published in the interests of medical societies are willing to publish the truth about proprietary remedies. In some respects they can not be blamed, because the existence of the journals depends on the income from these sources. He felt that the most valuable remedy is exposure; that as soon

as the truth is known concerning the ingredients of the nostrums, they will cease to exist. He said the society should cast its influence toward the passage of the bill for the regulation of food and drugs.

DR. A. B. HURSH thought that if societies would be somewhat heroic and not have for their official organs publications receiving such advertisements much good would be accomplished. He favored the holding of symposiums by the different branches of the County Society, the data of the same to be furnished the Committee on Legislation for further action.

DR. A. B. KIRKPATRICK cited a case showing all the evidences of chloral poisoning, the result of the use of one of the nostrums. He referred to the custom under some governments of having proprietary medicines analyzed by official chemists, the formula, with the correct price, printed and sent to the householders in the municipality. This naturally was a direct blow to the trade. He thought that some such plan in this country would be of advantage.

DR. FRANCINE thought the profession should support the American Medical Association in its work and endorse the work of the lay journals. He favored the appointment of committees to visit the lay editors for further accomplishment.

DR. ANDERS said that the best cure for the evil is continued exposure. This is to be carried on through the lay press in addition to the medical.

MR. WILBERT emphasized the necessity of the medical profession to devote the time to the correction of some of the phases of the fraud which is complicated and far-reaching. "Patent" medicines, he said, are called "patent," because they are not patented. The word "patent" means open, honest, evident, and there is nothing evident, except that the manufacturer is making money. "Ethical" means "honest," and there is nothing honest about a secret proprietary medicine. The greatest danger in regard to synthetic chemicals is the fact that the journals will not print a harmful effect when it is found. Physicians should acquaint themselves with the harmfulness of the various phases of the proprietary nostrum evil, be it called patent medicine, ethical remedies, or synthetic chemicals.

On motion of Dr. A. A. ESHNER, the following resolutions were adopted:

Resolved, That it is unidentified and unbefitting for physicians to prescribe medicinal preparations of secret or concealed composition and that the practice of so prescribing them is to be strongly condemned.

Resolved, That the Philadelphia County Medical Society heartily endorses the action of the American Medical Association in establishing a Council on Pharmacy and Chemistry for the purpose of investigating drugs of a non-official character.

BOSTON MEDICAL LIBRARY MEETING.

Regular Meeting, held Jan. 3, 1906.

DR. RICHARD C. CABOT in the Chair.

The Nostrum Evil.

The chairman had sent out to the profession, with the notice of the meeting, an abstract of an article from *Collier's Weekly* and distributed in the hall a partial list of the members of the Proprietary Association of America. In introducing the first speaker, Dr. Frank Billings of Chicago, he took occasion to explain the terms nostrum, patented medicines and patent medicines, proprietary remedies, etc.

DR. BILLINGS explained the relation between the terms "patented" and "copyrighted." One can not patent a mere mixture unless one patents the process by which it is made. Such a patent lasts seventeen years and is not really secret. But a copyright, usually of the name, lasts forever. Phenacetin is an example of the former class. Its patent expires in a few months. The patents protecting acetanilid and antipyrin have already expired. Gray's glycerin tonic is an example of the second class. A nostrum is a secret preparation, and the adjective, "secret" is really unnecessary. For the widespread use of nostrums this profession is primarily to blame. There are "millions in it." The doctors are dupes. The majority of physicians do not practice rationally. They make no real diagnosis, but note symptoms and treat them. Each symptom calls for a drug or drugs. Often these must be changed.

They must be palatable and the dose indicated. The physician is instructed (?) by the agent who brings him samples and who is either a doctor who has failed in practice or a druggist. Testimonials and explanations of the way in which the potency of the preparation is enhanced by a special method of preparation are believed and the latest sample employed. The nomenclature of nostrums is wonderful and without any semblance of system. Well-recognized drugs are used as a basis for a multitude of these preparations. Thus urotropin is the basis of at least twelve, and acetanilid of an even larger number. Poisons should be indicated on the labels and the exact amount contained indicated. Chronic acetanilid poisoning is a common occurrence in Chicago. Many of these products claimed to be synthetics are really simply mixtures. The acetanilid pulvis compositus of the new pharmacopoeia is a mixture too dangerous to use. This heterogeneous nomenclature is bad enough for medical progress, but even worse is the material published in the medical press containing the statements of what the given remedies will do. Examples were quoted from the *New York Medical Record*, *Medical News*, *Philadelphia Medical Journal*, *Boston Medical and Surgical Journal*, *American Medicine*, *British Medical Journal*, and *London Lancet*. Their absurdity was clear in the reading without comment.

THE JOURNAL of the American Medical Association has set an example which others should follow. The editor should be responsible also for the reading material in the advertisements. So far has this abuse progressed that the phrases used might with very little change be transferred *in toto* to the reading notices of such remedies as castoria or Ayer's cherry pectoral in the lay press. The medical press, with its great power for good as an educator, has an equal power for evil. Unfortunately, the editor edits only his part, and the publisher prints what pays him best. The average man believes what he reads.

The patent-medicine evil, then, is due, first, to the credulity, if not the ignorance, of doctors, and second, to the cupidity of proprietors and promoters, and of medical journals. Fifty per cent. of the doctors prescribe them. Mr. James J. Walsh of New York City reports that 70 per cent. of the prescriptions written there contain them. In one large Chicago pharmacy 42 per cent. of the prescriptions filled contained such ingredients and were signed by doctors of high standing. In another pharmacy 50 per cent. were of the same kind, and were sent by family physicians. For example, one prescription called for castoria and syrup of figs, 5ã, one teaspoonful every two hours. In Boston one drug store reports that of 14,895 prescriptions received in a year 38 per cent. contained proprietary medicines, and another had 48 per cent. in 12,000. In the country the proportion is even greater.

Modern medicine has shown that specific medicines for diseases are very limited in number. Medicines are mainly palliative or useful for the relief of organs. The doctor must first make a definite diagnosis and then seek to remove the cause. Besides hygiene, diet, etc., the pharmacopoeia furnishes an abundance of suitable drugs. A good druggist can fill any prescription desired and at far less expense than the corresponding nostrum. Thus acetanilid costs 30 cents per pound, but is sold in these preparations for 100 times that amount. Students should be better instructed in botany, materia medica and therapeutics. They should know when not to give drugs as well as when to prescribe them.

For the present evil the great remedy is publicity. Medical meetings should not be marked by the presence of great pyramids of proprietary remedies and stacks of literature. Testimonials should be frowned on. Advertising in the medical journals should be guarded; formulae with the exact amounts should be printed. The well-educated physicians do not wish to use a stock formula, but will adapt the prescriptions which they give to the individual needs of the patient.

Ready-Made Remedies.

DR. FRANK G. WHITELY of North Abington, house chairman of the committee on public health, Massachusetts General Court, 1904-1905, said he did not speak as a legislator, though incidentally he believes that both the commonwealth and the profession would be benefited if doctors were willing

more frequently to become members of the legislature. The medical profession is in some degree responsible for the present deplorable condition of affairs and has a certain duty to perform in the warfare against this evil. For practical purposes patented and proprietary medicines are alike. In either case the object is pecuniary gain. The duty of any worker in scientific medicine who discovers a new remedy of value or a new method of combining old remedies is as clear as that of the surgeon who has hit on some new method in operative surgery. To say that anything which has to do with the treatment of the sick should be restricted in this way is to say that the practice of medicine is commercialism pure and simple. The public is injured, physically, morally and financially, by these alleged remedies. While a few of them may be intrinsically valuable, in no single instance are they indispensable to the successful practice of the healing art, and the prescribing of them by the profession is, on the whole, a monumental blunder and works an endless degree of harm. Probably no one would prescribe peruna instead of the official *spiritus frumenti*, but, perhaps, some one might order listerine instead of a solution of boric acid. This robs the patient, for it has been demonstrated that as much antiseptic value can be obtained from a solution of any of the common antiseptics for one cent as from \$4.95 worth of listerine. Moreover, the physician by thus prescribing, throws his influence in favor of the whole class. The public is not logical, and jumps to this conclusion.

If better results are obtained by using them, it is because the average physician does not know enough about the science and art of prescription writing. This ignorance is one of the parts of a movement which dates back to Bigelow's "The Self Limitation of Disease," and has gone to the brink of therapeutic nihilism. Emphasis is laid on diet and hygiene, and drug treatment is considered of little moment. If this theory were applied to every branch of medical science we could very materially shorten the required courses in medical schools. Our medical students must be impressed with the fact that there are certain definite results which can be obtained by the use of drugs, and that a thorough knowledge of prescription writing is a *sine qua non* for a degree in medicine. Patients have the right to demand a prescription adapted to the individual needs of the case, rather than one ready-made which has to recommend it the dictum of a financially interested manufacturer. Medical schools should produce graduates who can write individual prescriptions. Not long since there was formed in Paris an association for the postgraduate study of drugs, the reason given being that the average French graduate knows little or nothing of the subject.

A second reason for using the ready-made article is that it is easier to order it. True, but it would be easier still and in most cases better to prescribe nothing. The leaders in the profession lessen the validity of their claim by so prescribing and give proof of lack of education, laziness or ape-like imitativeness. Commercialism is back of the whole subject. Any legislation which interferes with the business is sure to encounter tremendous opposition. The fellow-townsmen of Lydia Pinkham, J. C. Ayer & Co., and the residents of other municipalities where the business is carried on, advertising agencies and the drug trade, with some honorable exceptions, join forces with the manufacturers and prevent legislative interference. The time has come when there are no "ethical preparations." We should ignore the whole list. If we will confine our prescribing to articles recognized by the national authority, we shall confer one of the greatest boons on the public and incidentally on ourselves that the annals of medicine record.

Dr. DAVID W. CHEEVER said that physicians have two duties, that which they owe to their patients and that which they owe to the public. He must first find out what is the matter and then give not an opinion, but a remedy. This may be advice as to hygiene and sanitation, or it may include drugs, and the physician should know the character, qualities and purity of those drugs. Prescriptions which are made up at the time by a reliable apothecary are likely to be pure and fresh and, therefore, potent. The great danger in all these secret remedies is that the manufacturers either do not state what they contain, or make false statements regarding the

composition of these remedies. Drugs especially dangerous in such preparations are opium, chloral, cocaine, the coal-tar products, and last but not least, alcohol. If a physician prescribes an unknown remedy and a drug habit results, it is certainly as much his fault as that of the manufacturer.

Dr. JAMES C. WHITE said that though in practice fifty years, he had never prescribed a single remedy outside of those contained in the pharmacopœia. The success of nostrums and proprietary medicines lies in the advertising. The daily press, the religious press, literary weeklies, monthlies and quarterlies, and even the medical press, are all at fault. Medical journals should have no nostrum advertisements. A few medical journals adopting this plan would have general support and would not need to depend on advertisements for their pecuniary success. A medical journal with which Dr. White is connected, which has only twenty advertisements, can not pay its way at \$4 a year, while a similar journal with seventy advertisements is entirely self-supporting at \$1 a year. Agents of proprietary medicines should be kept away from the physician's office. Dr. White would establish in every locality a pharmacy which would agree to have no dealings with proprietary remedies and to supply only pharmaceutical preparations. He believes that at least 50 per cent. of the profession would support such a pharmacy.

Dr. MORRIS PRINCE believes that if a medical journal would exclude nostrums and appeal to the medical public it would receive support. This would be a duty. Advertisements are put in because the profession does not give the needed support. Dr. Prince referred to the work of *Collier's Weekly* and to the exposure by the *Ladies' Home Journal* of the methods of manufacturers in advertising for correspondence regarding various ailments. These letters, he said, are classified and answered by stock letters. Dr. Prince stated that this is a fraud in that it violates state law by practicing medicine without a license. A patent medicine is not a success unless it is a "repeater." Frequently this means that a drug habit like alcoholism has become established and can be broken off only with great difficulty. Proprietary medicines whose ingredients are known and whose manufacture is conducted by honest business methods may be useful. The evil of those whose ingredients are not known, Dr. Prince said, might be remedied by the publication of their formula. For many years he has received no agents at his office, and now no agent goes there to leave samples.

Dr. F. C. SHATTUCK spoke of the "Index Medicus." There are no advertisements in that journal. Though only valuable for every library, it was not supported by the profession even when the price was only \$5 a year. It was allowed to die and was revived by Mr. Carnegie's money. The medical men are the recipients of his bounty.

Dr. JOHN LOVETT MORSE said that we can hardly fail to appreciate the importance of this subject. Physicians realize their indebtedness to the Council on Pharmacy and Chemistry of the American Medical Association. He thinks that physicians ought to realize also how much they owe to the *Ladies' Home Journal* and *Collier's Weekly* for bringing this to the public. These magazines reach the public where doctors do not. Dr. Morse presented the following resolutions:

Resolved, 1. The members of the Suffolk District Section of the Massachusetts Medical Society here present heartily approve of the action of the American Medical Association in establishing the Council on Pharmacy and Chemistry for the purpose of investigating and reporting on non-official drugs and cordially welcome the results of the work already done by that Council.

2. We also our hearty support to the educational campaign now being carried on by *Collier's Weekly*, by the *Ladies' Home Journal* and by THE JOURNAL of the American Medical Association and we warmly commend the action of these journals in exposing the humiliating subordination of the press, lay and medical, to the manipulations of the Proprietary Association of America, and in showing up the fraudulent use of sham testimonials and the loss of life due to the use of the products exploited by members of the Proprietary Association.

3. Copies of these resolutions should be sent to journals mentioned in the foregoing resolutions.

This resolution was unanimously adopted.

Dr. CAMERON suggested one other remedy, namely: If the 200 or 300 physicians who are contributors of articles to the best of medical journals would refuse to allow their papers to be printed in any journal which admits nostrums to its advertising pages, their influence might be decisive.

WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Fifteenth Annual Meeting, held in Kansas City, Mo., Dec. 28-29, 1905.

(Concluded from page 148.)

Treatment of Appendicitis.

DR. O. BEAUFY CAMPBELL, St. Joseph, Mo., summarized his paper as follows: 1. In incipient appendicitis, until the patient is placed in the hands of the surgeon, all food and drink should be withheld, and the patient nourished per rectum. 2. Every patient should be advised of the advantages of an early operation. 3. The removal of the appendix, or the closure of an opening in the cecum, should be made, in abscess cases, when it can be done without additional risk to the life of the patient. 4. The practice of merely draining in every abscess case should be condemned as nonsurgical. 5. Operation during a progressive diffuse peritonitis is attended with a higher mortality than the method of procedure recommended by the writer. 6. If the internist will direct his efforts in the treatment of appendicitis toward the protection of the peritoneum until he can transfer his case to the surgeon, the mortality in this disease will be greatly lessened. 7. The adoption of the more rational method of dealing with diffuse peritonitis will convert a large percentage of these cases into circumscribed peritonitis, when they can be rightly classed as large abscess cases, having the same mortality.

Treatment of Appendicitis in Its Various Stages as It Comes to the Surgeon.

DR. C. H. WALLACE, St. Joseph, Mo., summarized his paper as follows: 1. Appendicitis is always a surgical case. 2. Every case should have and is entitled to operative measures within the first forty-eight hours. 3. The rapidly progressing stage is the stage of applicability of the Ochsner treatment, and by it offers the lowest mortality. 4. Cases coming to the surgeon with evidence of gradually subsiding symptoms should be deferred for a more favorable operative period. 5. In every interval or chronic case operation should be urged. 6. Abscess cases should be given two safe rather than one hazardous operation. 7. Diffuse peritonitis should have all accumulated dependent cavities primarily and carefully incised and drained and not flushed, and secondarily the offending organ incised.

Extrauterine Pregnancy.

DR. J. W. ANDREWS, Mankato, Minn., reported having operated on a woman who was ten weeks pregnant; the sac ruptured and the operation was delayed thirty-six hours. The steps of the operation performed were not very different from those of an ordinary laparotomy. He argued in favor of accuracy and rapidity in operating on these cases, and emphasized the necessity in many cases of thrusting the hand down through the pool of blood and securing the blood vessels before attempting to mop out or otherwise remove the blood and blood clots. He thought drainage, as a rule, should be employed after laparotomy for extrauterine pregnancy.

Postclimacteric Hemorrhages; Their Cause and Treatment.

DR. A. L. WRIGHT, Carroll, Iowa, called attention to the frequency of occurrence of postclimacteric hemorrhage after the establishment of the menopause. He spoke of how often it is passed over slightly, with the thought that it is incident to the woman's age until grave complications are at hand, or the true cause—carcinoma, in most instances—is so far advanced as to place the patient beyond the pale of surgical interference. Dr. Wright called attention to the several changes that take place in the uterus at this time and cause hemorrhage. The trend of his argument was to early recognize the pathologic changes taking place in the uterus, and, if in doubt, remove the organ rather than take chances that will invariably result in death.

Gunshot Injuries of the Stomach.

DR. J. N. WARREN, Sioux City, Iowa, gave the history and analysis of 141 cases of gunshot injury of the stomach. In operated cases the time elapsing from the time of injury and

the operation shows that the earlier the operation is performed the more favorable is the result. In complicated cases the number of lesions found and viscera injured add to the gravity of the case. He referred to the results in cases that were not operated. He said the presence of food in the stomach, with the discharge of the same into the abdominal cavity, adds to the danger of general peritonitis, either with or without operation.

Symptoms of Spinal Disease.

DR. S. C. BALDWIN, Salt Lake City, Utah, called attention particularly to the early symptoms of spinal disease, in order that suffering may be earlier relieved and deformity avoided. The general or more common symptoms, and then such symptoms as rigidity, abnormal gait, pain, paralysis, abscess, etc., were considered. The symptoms differ when different regions of the spine are involved. For instance, in the cervical region the first symptom noticed may be pain in the head, or earache. Before there is any sign of deformity the patient may complain of difficulty in swallowing and even in breathing. There may be and often is the grunting respiration. Such general symptoms as weakness, loss of appetite, loss of weight, rigidity and general change of gait are apparent in disease of all parts of the spine. The writer has seen a number of cases of Pott's disease developing in patients over 40 years of age, and two cases which he recalls developed after 50. Weakness may show itself in a general drooping of the trunk, in an unsteady and stumbling gait, and exhaustion requiring rest after the slightest exertion.

Drainage of the Male Pelvis.

DR. WILLIAM JEPSON, Sioux City, Iowa, spoke of the obstacles in the way of instituting such drainage as compared with the female pelvis. He described a method of instituting drainage of the male pelvis and reported the results he obtained in 19 cases. In all of these cases there existed a diffuse pelvic peritonitis, with accumulations of purulent fluid, often elevating the distended bowel high into the abdomen, and in two cases ascending between the mesentery and descending colon and overflowing from the pelvis into the left subrenal fossa, which was also opened and drained. In all but five cases free pus existed in the space to the outer side of the ascending colon, which in each instance was drained through the ileocecal space. In one case the distended parietic bowel necessitated opening and the establishment of an artificial anus. Three of the cases thus treated died, one after an illness of nearly five months, during which time death on three or four occasions was threatened by intestinal obstruction, while a number of abscesses followed in the abdominal wall. Death resulted from exhaustion incident to the prolonged suppuration. In the second fatal case death took place ten days after the operation, due to toxemia.

Gastric Dyspepsias Amenable to Surgical Treatment.

DR. WILLIAM E. GROUND, Superior, Wis., said it is now recognized that many forms of digestive disturbance are dependent on conditions entirely outside the stomach, and involve this organ either by direct extension of the pathologic process, or indirectly by nerve influence. Among these may be mentioned inflammatory or irritative conditions in the biliary apparatus, pancreas, duodenum, or appendix, and adhesions of the stomach to the surrounding viscera. Within the stomach conditions remediable by surgical means are perforative and non-perforative gastric ulcer, chronic gastric ulcer, hemorrhage, pyloric obstruction, gastric dilatation with stasis, hyperchlorhydria, and cancer. The question of operative interference in some of these conditions is still in dispute, but the wisdom of referring cases of perforating gastric ulcer, with or without adhesions, cicatricial stenosis of the pylorus, adhesions of the stomach to any of the surrounding structures and perhaps chronic gastric ulcer, to the surgeon is now quite firmly settled.

Closely associated with ulcer is the sequence of cicatrization and contraction, and when this process involves the pylorus, it leads to stenosis and obstruction, and later, if this is prolonged, gastric dilatation and atony will result. When the

pylorus is obstructed by spasm due to the presence of the ulcer or to hyperchlorhydria, which almost always accompanies non-malignant ulcer, or to the electrical contraction following the healing of an ulcer, the pylorus is rendered incapable of readily transmitting its contents, the stomach becomes distended, and its muscular walls weakened, leading ultimately to permanent atonia gastrica. Stomach dilatation may be due to atony alone, but it is much more frequently due to mechanical obstruction at the pylorus. In this condition of gastric stasis, food may remain in the stomach a day or more, whereas it should empty itself within seven days at the most. In fairly advanced cases, when the obstruction has given rise to a compensatory hypertrophy of the stomach, the peristaltic movements may be seen and felt through the abdominal walls, usually accompanied by pain and vomiting. Later, when the stomach begins to dilate and assumes a more passive state, the patient complains of fullness and epigastric pains after meals. Fermentation takes place, causing eructations and heartburn, and frequently vomiting. Vomiting is a most prominent symptom when gastrectasia and fermentation are well established. When this sequence of events is set up there is but one remedy, and that is surgical intervention.

In view of the information of the curative effects of operation, they can not be attributed alone to drainage of the stomach or to short circuiting of the food current, as is so often contended, for unless the pylorus is closed food will pass through it. The explanation the writer has arrived at is that the cutting off of the circular fibers in the pyloric end of the stomach does away to a considerable extent with the muscular unrest accompanying gastric digestion, especially where ulceration is present. A gastroenterostomy acts much the same as cutting the fibers of the sphincter ani in anal fissure. In this latter condition the feces continue to pass over the ulcer, but the paralyzed sphincter prevents friction and it heals readily.

Restoration of the Perineum.

DR. HOWARD HILL, Kansas City, Mo., said that the ideal operation consists in restoring the different planes of tissue to their normal position. He has used a transverse incision which raises a flap of the posterior vaginal wall and has done the operation by using three layers of sutures. The first includes the levator ani and its fascia, reattaching that portion of the muscle which helps to form the perineal center in front of the rectum. Next he identifies and sutures the triangular ligament and attaches the sphincter ani to the perineal center. A single suture is used for the bulbo-cavernosus.

Preoperative Thrombi in Field of Operation as a Cause of Postoperative Complications and Death.

DR. A. W. ABBOTT, Minneapolis, Minn., said that thrombosis, especially of the veins, is often to be found, if looked for, in the vicinity of the field of operation. Thrombi may result from the pressure of a tumor, from cancer, or tuberculosis, etc., or they may be the result of adjacent inflammation or traumatism. Usually no attention is paid to the condition. Thrombosis in the field of operation increases the danger. The author believes many cases of fatal sepsis, pulmonary embolism, and particularly cases of so-called ether pneumonia, can be rightly ascribed to the infection of a clotted vein or its disturbance by rough handling, or both; so also pyemia, abscess of the liver, osteomyelitis, and other evidences of a metastatic infection. Aural surgeons have formulated a definite operation for thrombi of the lateral and sigmoid sinuses, namely, ligation of the internal jugular vein and clearance and drainage of the sinuses. He thinks a similar course should be pursued in all operations complicated by thrombosis.

Conservatism in Postoperative Treatment.

DR. S. C. BURDE, David City, Neb., criticised the increasing tendency among surgeons to hasten their patients out of bed and hospital after grave operations. Nature will work only so fast, and he thinks there is a limit in time beyond which it is unsafe to urge her. He contends that this limit has been overstepped, and that the perfect result which should be the aim in every case is thereby marred.

The following papers were also read: "Talipes Calcaneus," by Dr. A. F. Jonas, Omaha; "Tubercular Peritonitis," by Dr. T. E. Potter, St. Joseph, Mo.; "Management of Appendicitis Cases," by Dr. Van Buren Knott, Sioux City, Iowa; "Gluteal Cavernous Angioma," by Dr. J. E. Summers, Jr., Omaha.

THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

SECTION ON GENERAL MEDICINE.

Regular Meeting, held Nov. 13, 1905.

The president, DR. SAMUEL M. HAMILL, in the Chair.

Medical Versus Surgical Treatment of Stomach Diseases.

DR. FRANK BILLINGS, of Chicago, presented an elaborate paper which will appear in THE JOURNAL.

Indications for Surgical Intervention in Diseases of Stomach in the Absence of Perforation or Hemorrhage.

DR. GEORGE E. BREWER, of New York City, stated that the question of treatment of gastric and duodenal disorders can be settled only by careful review of reliable statistics regarding the end-results of cases treated both medically and surgically. There is not recorded a single case of carcinoma cured by medical treatment. Surgery has cured from 12 to 15 per cent. of cases submitted to radical operative treatment at a time when the disease could be completely removed. Surgery also gives great temporary relief in a large number of cancer cases which have passed beyond the period where radical operation is advisable.

The surgical treatment of gastric ulcer has shown results far in advance of those published from the best medical clinics of the world. The statistics of Greenough and Joslin, who followed and obtained the end-results of 187 cases of gastric ulcer treated at the Massachusetts General Hospital, show that, while 80 per cent. were reported as cured at the time of leaving the hospital, only 40 per cent. remained well, and that, while the hospital death rate was stated as 8 per cent., the actual death rate from the disease was found to be 20 per cent. Russell's statistics, published in *The Lancet* for January, 1904, show even a smaller percentage of final cures by medical treatment. These statistics conclusively demonstrate that 60 per cent. of all cases of gastric ulcer treated medically must look forward to death or chronic invalidism. The statistics of von Eiselsberg, Mayo, Deaver, Robson, Munro and others show from 50 to 90 per cent. of positive cures by operation.

Regarding the treatment of pyloric stenosis from ulcer or other causes, he said it might be stated positively that in no other diseases of the alimentary canal are the results of surgical treatment more strikingly satisfactory. von Eiselsberg reported 90 per cent. of his cases cured on an average of two years after operation. Mumford collected the end-results in 169 cases from 8 different surgical clinics. Of these he reported that 89 per cent. were immediately relieved of their symptoms as the result of operative treatment, while 71 per cent. remained permanently cured. The death rate from gastroenterostomy has been so reduced that at present, in the hands of expert operators, it should be less than 3 per cent. These facts, he thinks, conclusively demonstrate the superiority of surgical treatment in this class of cases. Regarding the surgical indications in diseases of the stomach and duodenum Brewer stated: 1. All cases of perforation of an ulcer of the stomach or duodenum should be immediately subjected to surgical treatment. 2. Repeated attacks of hemorrhage, threatening the life of the individual, should be treated surgically. 3. Exploratory operation should be advised in all cases of suspected cancer to establish the diagnosis and to render it possible to inaugurate radical treatment at a time when the disease can be thoroughly eradicated. 4. Gastroenterostomy should be advised in all cases of gastric cancer with pyloric stenosis before the patient becomes exhausted from suffering and starvation. 5. All cases of gastric ulcer not relieved by six weeks of intelligent medical treatment, all cases of chronic indurated ulcer, and all cases of recurrent symptoms from unhealed ulcer should be subjected to surgical treatment. 6. All cases of progressive pyloric stenosis from

whatever cause, except those due to gummatous infiltration, should be referred to the surgeon as soon as the diagnosis is made.

Relation of Carcinoma to Ulcer of the Stomach, Especially as Influencing the Treatment of Ulcer.

DR. JOHN H. MUSSER said that, in view of the conclusions of Fütterer, of Chicago, in his study of some 56 cases of carcinoma of the stomach, the origin of which was in the site of an ulcer—namely, that ulcer of the stomach was followed by and might, perhaps, be considered in one sense causal of carcinoma of the stomach—and, in view of the fact that in 8 per cent. of all cases of carcinoma of the stomach a clear family history of carcinoma could be obtained, he thought it fair to the patient with a chronic ulcer of the stomach, in whom there was a family history of cancer, not amenable in six or eight weeks to medical treatment, to operate. If acute gastric ulcer can be diagnosed, medical treatment should be employed; but, in the large majority of cases, it is difficult to determine whether or not the condition is an acute manifestation of a chronic ulcer. Chronic ulcer might remain latent over a long period and suddenly manifest acute symptoms, such as hemorrhage. Such an occurrence in a patient over 40 years of age should be managed as one of chronic ulcer. In both classes of cases, however, there should be the individual study of the case. Carcinoma of the stomach, if diagnosed early, should be at once treated surgically. In cases of doubt he advised exploratory incision. He unhesitatingly demands operation in pyloric stenosis due to adhesions of all kinds. In cases of supposed ulcer where the diagnosis rested between pyloric stenosis due to ulcer and stenosis due to adhesions, if medical treatment has been unavailing, in a very short time he advises immediate operative procedure. In the doubtful differential diagnosis of pyloric stenosis due to adhesions and that of carcinoma, immediate surgical intervention was urged on the ground that if the stenosis were benign the patient would be relieved; if malignant, the patient would be given the benefit of the best chance. Dr. Musser thinks all are in accord with Dr. Billings regarding the inadvisability of operating generally in cases of ptosis and in cases of gastric neurosis in which there had occurred organic lesions, although occasionally operation brought about cure. An illustrative case was cited of a woman who for five years had been under the best medical care to overcome the neurasthenic condition, associated with ptosis and extreme gastric dilatation. Finally operation entirely relieved the dilatation, and after a period of 8 months the general phenomena disappeared. The patient gained 50 pounds, and is at present perfectly well. Dr. Musser concluded by saying that, while there are some cases in which the indications for operative procedure are positive, there are numbers which should be under careful medical attention for some time, but not too long, and that now and then a neurasthenic subject is cured only by surgical means. He said that he would rather give the patient the advantage of an exploratory operation by a competent surgeon, in cases in which the diagnosis is doubtful, than allow them to rest in the too often false security of a dogmatic diagnosis. He has never had reason to regret surgical procedures, while he has been chagrined at its non-employment in three cases that died of hemorrhage.

Final Results of Gastroenterostomy and Pyloroplasty in Stomach Diseases.

DR. JOHN B. DEEVER said that chronic non-malignant gastric affections of the stomach are attributed largely to ulcers of the stomach which produce various grades of gastric indigestion. He did not believe that the stomach exists as an isolated organ, but that it forms a part of the digestive apparatus found in the upper abdomen. Pathologic experience has shown that persistent gastric indigestion depends for its chronicity on structural organic change which can not be remedied by medical and dietetic measures. In support of this the figures of Hartmann were given of a mortality of 2 per cent. in cases treated surgically and of 24 per cent. in those cases primarily treated medically and later referred to the surgeon.

The two main therapeutic objects of gastroenterostomy and pyloroplasty are rest and drainage of the stomach. In gastric

ulcer without pyloric stenosis or dilatation of the stomach, rest is the main therapeutic object. Hemorrhage, chronic in nature, is an important symptom produced by ulcer of this character, and for this symptom the surgeon's aid is most frequently sought. The value of nutrient enemata for putting the ulcerated stomach to rest, he felt, has been overestimated. Edsall had shown that, even under the best conditions possible, patients fed only by nutrient enemata are slowly starving to death. To secure this required rest, surgery short-circuits the ingested food so that when it is received into the stomach it passes directly into the jejunum by an artificial opening and never comes in contact again with the ulcerated pyloric area. Among the last 38 operations performed by Dr. Deaver for non-malignant diseases of the stomach there has been one death, a mortality of 2.63 per cent. This death occurred in a patient with chronic Bright's disease, who also had chronic appendicitis, the appendix being removed at the time the stomach operation was performed. Dr. Deaver said it should be remembered that figures given for the surgical side of the argument include not only operations to procure rest to the stomach in patients with non-stenosing ulceration, but many operations on stomachs very extremely diseased, also that the operative mortality is constantly lessening. Mumford found that of the cases treated by medical means and apparently cured, averaging about 80 per cent. of the whole, probably one-half did not remain cured. With surgical treatment Mumford's figures were given as follows: Of 7 patients Barling had, 7 remain cured; of 28 Mayo had, 27 remain cured and only 1 had recurrence of symptoms; of 37, Moynihan succeeded in tracing 29 and found that all were permanent cures; of 28, Mayo Robson traced about 20 and learned that they were all permanently cured. Dr. Deaver traced 30 patients operated on by himself and all had entire immunity from digestive disturbance. It was urged that surgical treatment allowed from 95 to 98 per cent. of these patients to recover from the operation; medical treatment, from 70 to 80 per cent. from its treatment; that surgery practically cures every patient who recovers, and that medicine permanently cures only 40 to 50 per cent. of its patients; that medical treatment is long and uncertain; surgical, rapid and sure. Dr. Deaver does not urge surgical intervention in every case of ulcer of the stomach; for instance, acute peptic ulcers are frequently cured by medical rest and by therapeutics founded on the well-known physiologic laws elaborated by Pawlow. The second object of surgical intervention is that of drainage. This is indicated in practically every case of pyloric obstruction. He does not favor the operation advocated by Beyer, that of shortening the lesser omentum, because of the danger of wounding important nutrient blood vessels and because dilatation is not materially aided and probably will increase. The problems of the proper treatment of gastric diseases, Dr. Deaver believes, can only be worked out by the physician and surgeon together. He urged that the surgeon be called earlier in consultation that, with the aid of his medical colleague, he might decide which are the proper cases for surgical treatment and at what period of the disease surgical treatment can with best advantage be applied.

Therapeutic and Prognostic Value of Occult Blood in the Stools.

DR. J. DUTTON STEELE said that the conditions in which the test for occult blood in the feces are of prognostic and therapeutic value in the course of gastric ulcer are as follows: 1. To determine the length of the various periods of the medical treatment of ulcer. The patient should be kept on liquid diet and at rest until all bleeding has stopped. 2. To detect the tendency to bleeding during the course of gastric ulcer and by appropriate medical and surgical means to anticipate and prevent serious hemorrhage. 3. To determine when the medical treatment may be considered to have failed and surgical treatment is needed. This is indicated by repeated recurrence of bleeding when the patient is started on solid food after being on liquid diet. 4. Perhaps the best test may prove helpful under certain circumstances in detecting the development of a cancer on the floor of an ulcer; as, for instance, when the bleeding recurs and will not stop, although the patient is on a milk diet and in bed.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns.]

Treatment of Bronchitis in Children.

Clinical experience, according to Joseph E. Winters, in *Medical News*, teaches that bronchitis in young children is never mild. A slight coryza may rapidly spread to an involvement even of the small bronchi within twenty-four hours. In the treatment of bronchitis the temperature of the room should be uniformly at 72 F., both day and night. The room should be so situated as to admit the sun's rays and an open fire should be present, if practicable. Fresh air must be the rule at all hours. The child, according to Winters, should be in a crib and not in a bed. The crib should be flannel lined and placed in the center of the room, never near a wall, window or door. Screens should be placed about the crib for protection against draughts of air. The child should be clothed in light flannel, both arms and legs. The shirt should be loose and open in front, secured by safety pins, so that ready access may be had for physical examination. In cases of moderate severity this treatment is all that is required.

MEDICINES.

In severe cases this author recommends aconite as a remedy of perhaps the greatest efficacy, in order to restrain and to limit the amount of blood to the arteries. This preparation limits the arterial pressure and should be given in frequent doses during the first hour, gradually diminished after four or six hours, and not continued for any great length of time. He recommends the following combination for this purpose:

R. Tinct. aconiti. m. iv 25
Aque dest. 3iij 90

M. Sig.: One teaspoonful every fifteen minutes for one hour; every half-hour for four or six hours; then every hour for twenty-four hours.

The foregoing is the correct dose for a child of 1 year.

Arterial pressure is also lessened by means of diaphoresis, and as a diaphoretic he recommends spiritus etheris nitrosi as without an equal in such cases. Potassium citrate and liquor ammonii acetatis may be used in a similar manner. These preparations, however, more frequently cause nausea and so affect the sense of taste of the child, on account of this disagreeable effect, that nourishment is persistently refused. Intestinal elimination must also be properly looked into. Baths or sponging are not so necessary in these cases, according to this writer, as he states that cold to the cutaneous capillaries is an unphysiologic procedure and pernicious, and tends to extension of the disease.

STAGE OF SECRETION.

In the stage of excessive secretion agents must be employed which tend to diminish this condition. These are camphor, carbonate of ammonia, nux vomica, oxygen inhalations and counter-irritation. He recommends the spirits of camphor as the most valuable agent, and for a child 1 year of age he prescribes the following combination:

R. Spiritus camphoræ 3i 4
Saccharin gr. i 106
Spiritus etheris nitrosæ 3iij 8
Syrupi lolutani 5iv 15
Aque gaultheria, q. s. ad 3iij 90

M. Sig.: One teaspoonful every half-hour.

In the foregoing prescription the sweet spirits of nitre is added to prevent the precipitation of the camphor, and the syrup of tolu diminishes the pungency of the mixture.

The ammonium carbonate in one-grain doses is a valuable addition to the foregoing mixture unless it provokes nausea.

When the bronchi are loaded with tenacious secretion mustard is of valuable service. A paste composed of six parts of flour, one part mustard, and mixed with cold water and the white of egg, and covering the entire region over which the

moist râles are to be heard, is recommended, and allowed to remain for twenty or thirty minutes, and renewed at intervals of from two to four hours, according to the condition of the skin.

When the air tubes are blocked by tenacious muco-purulent secretion they may be freed by active emesis. This method of treatment should not be repeated more than once or twice in the twenty-four hours, and the child must be kept in the prone position to secure gravitation of secretions to a sensitive mucous membrane, in order to avoid reëfilling.

In cases of laryngo-tracheitis and tracheobronchitis, in which a harassing cough is present, indicating inflammation of the upper respiratory passage, oleum ricini is recommended, combined as follows:

R. Olei ricini 5iv 15
Saccharin gr. ii 12
Pulv. acacie q. s.

M. Ft. emulsi et adde:

Spiritus etheris nitrosæ 5i 30
Aque calcis q. s. to make 3iij 90

M. Sig.: A teaspoonful every hour.

When the cough is exceedingly distressing, counter-irritation over the larynx and sternum should be added to the treatment by the application of flaxseed poultice with mustard sprinkled over the surface. In older children Winters recommends in those irritating coughs superinduced by nervous irritability, that small doses of codin be given. In inflammations of the larynx, trachea, or bronchi, with much temperature present, he recommends aconite as the most efficient preparation.

Counter-Irritation.

Wainwright, according to an abstract in the *Medical Standard*, states that counter-irritation may be resorted to for three purposes: First, to relieve pain; second, to lessen congestion and inflammation of deep-seated organs, and, third, to promote the absorption of the products of inflammation. Counter-irritants are divided into three classes: First, rubefacients; second, vesicants, and, third, pustulants. Rubefacients do not destroy the structure of the skin, but simply cause a mild irritation and redness of the surface. They are employed essentially in functional disturbances. Vesicants cause structural changes in the skin and the underlying tissues, and are of service in chronic affections, or in those cases in which there has been a permanent change in the organs or tissues following inflammation. The third class cause pustular eruption. The author mentions as the best rubefacients mustard plasters, pepper, iodin, turpentine, and as vesicants the actual cautery, caustics, setons; as pustulants he believes that croton oil and tartrated antimony are the best. The croton oil as a pustulant must be diluted one-half with olive oil before application. The local effect of rubefacients is the same as that of acute inflammation, by producing irritation of the nerve terminals, redness, swelling, etc. He speaks of blisters as being contraindicated in gout and in diabetes, in aged individuals, and in debilitated or anemic patients, because sloughing is so liable to occur. Sawyer, according to this abstract, recommends the use of a preparation of capsicum as a rubefacient. He has found that an ethereal tincture of capsicum, by the reason of rapid evaporation of its ether, is of more value than an alcoholic tincture of the same preparation. He recommends as an excellent rubefacient the following combination:

R. Tinct. capsici ether. |
Liquor ammonie |
Olei tercbenthine |
Olei lini, aa. 5iv 15

M. Sig.: Apply locally on flannel cloth or spongio piline.

Vaginitis.

The following combination is recommended by the *Medical Review of Reviews* in the treatment of vaginitis:

R. Pulv. aluminis |
Zinci sulphatis |
Sodii bicarbonatis |
Acidi carbonici, aa. 3i 30
Aque 3vi 180

M. Sig.: A teaspoonful to a quart of lukewarm water, as a vaginal douche, twice daily.

For prostatitis the following combination is recommended by the same periodical:

R. Ext. opii aq.....	gr. viii	50
Ext. hyoseyami.....	gr. iv	25
Olei theobroma, q. s.		

M. Ft. suppository No. viii. Sig.: Insert one suppository into the bowel, and repeat as necessary.

Erysipelas.

Mortimer, in *Merk's Archives*, recommends as prophylactic measures in the treatment of erysipelas that the patient be isolated and all dressings burned when removed. Small doses of calomel should be administered at intervals of one hour for six or eight doses, followed by a saline purgative. During the first twenty-four hours one-minim (.06) doses of tincture of aconite should be given every two hours. Alcohol may be given as a stimulant, if required, or as a substitute strychnia or nitroglycerin may be given. An icebag may be applied to the head to relieve the pain, and in addition to that the following combination may be given:

R. Caffeine citrate		
Camphore monobromate, aa.....	gr. ss	103
Acetanilid.....	gr. ii	12

M. Ft. cap. No. i. Sig.: One such capsule every two hours. Locally the following is recommended:

R. Tinct. opii.....	3i	30
Liq. plumbi subacetatis.....	5ii	60
Aque dest.....	vi	100

Sig.: To be applied locally on compresses.

Liquid nourishment should be given systematically every three hours. Ice-cream may be given, and cold water should be given freely. During convalescence the general tonic treatment is indicated, with some form of iron, or as follows:

R. Strychnine sulphatis		
Acidi arsenosi, aa.....	gr. 1/50	0012
Extracti gentiane.....	gr. ss	03
Quinin sulphatis.....	gr. ii	12

M. Ft. cap. No. i. Sig.: One such capsule after meals. Or:

R. Strych. sulphatis.....	gr. 1/4	015
Liquor ferri et ammon. acet.....	3vi	180

M. Sig.: One tablespoonful in water after meals.

Medicolegal

Use of Skeleton to Illustrate Testimony.

The Supreme Court of Illinois says that, in *Chicago & Alton Railroad Company vs. Walker*, a personal injury case brought by the latter party, physicians who testified on behalf of the plaintiff were permitted, over the objection of the defendant, to use the skeleton of a human foot in explaining to the jury the location of the various bones and ligaments of the ankles. This court thinks the ruling in that regard unobjectionable. It says that the skeleton itself was not offered in evidence, but was simply used by the expert witnesses to illustrate their testimony. The court might, in its discretion, have permitted the plaintiff to exhibit her injured ankle to the jury, and allowed physicians to explain from it the nature and character of the injury. It was equally proper to use the skeleton for the purpose of explaining the testimony. Moreover, even if the skeleton had been improperly used, no substantial injury could have resulted therefrom to the defendant, as its counsel had full opportunity to cross-examine the witnesses.

Indirect Use of Medical Works in Framing Questions.

The Court of Appeal, First District, California, says that, in the homicide case of *People vs. Bowers*, a physician who had given testimony as to the symptoms and effects of arsenical poisoning was asked by the district attorney this question: "Is this a correct statement: While the poison is being eliminated, the process which begins very soon after it is taken, it generally causes fatty degeneration of the liver, heart, and kidney. The symptoms of which are often very prominent?" This was objected to on the ground that it appeared that the district attorney was reading from certain medical books and asking the witness questions therefrom. It has been held, in

California, that it is not competent on the examination of medical witnesses to read to them extracts from medical works and ask them whether what is so read corresponds with their own judgment, when it is apparent that the sole object of so doing is to place before the jury the opinion of the author of the books referred to. But from the record in this case it did not appear, except for the statement of the attorney for the defense, that the jury could have known that the district attorney was, in fact, reading from a medical book, or from any book. So far as appeared, if in fact he was reading his question from a book, it was entirely out of sight of the jury. Moreover, when the objection was raised, the district attorney said that he was making this his own question. The court says that, while the course adopted by the district attorney could not be commended, it does not think that it would justify a reversal, or that actual error had been shown.

No Damages for Mere Mental Disturbance.

The Supreme Court of Pennsylvania says that it had the personal injury case of *Huston vs. Borough of Freemansburg* reargued before the full court to settle finally the question that there can be no recovery of damages from fright or other merely mental suffering unconnected with physical injury. It says that the industry of counsel furnished it with a few cases favorable to his contention not previously considered. But they did not show any sound reason for a change of the court's view. All of the cases were of recent and unhealthy growth, and none of them stood squarely on the ancient ways. In the last half century the ingenuity of counsel, stimulated by the cupidity of clients and encouraged by the prejudices of juries, has expanded the action for negligence until it overtops all others in frequency and importance; but it is only in the very end of that period that it has been stretched to the effort to cover so intangible, so untrustworthy, so illusory, and so speculative a cause of action as mere mental disturbance. It requires but a brief judicial experience to be convinced of the large proportion of exaggerated, and even of actual fraud, in the ordinary action for physical injuries from negligence; and if the court opened the door to this new invention the result would be great danger, if not disaster, to the cause of practical justice. If, therefore, the question were new, this court should see no reason to reach a different conclusion. But it is settled for this state, and is no longer open to discussion.

Criminal Negligence and Liability—"Intestines."

The Supreme Court of Florida, Division B, holds, in *Hampton vs. State*, that where the death of a person results from the criminal negligence of a medical practitioner in the treatment of the case the latter is guilty of manslaughter. This criminal liability is not dependent on whether or not the party undertaking the treatment of the case is a duly licensed practitioner, or merely assumes to act as such, acted with good intent in administering the treatment, and did so with the expectation that the result would prove beneficial. The real question on which the criminal liability depends in such cases is whether there was criminal negligence. Such criminal negligence is largely a matter of degree, incapable of precise definition, and whether or not it exists to such a degree as to involve criminal liability is to be determined by the jury. Such criminal negligence exists where the physician or surgeon, or person assuming to act as such, exhibits gross lack of competency, or gross inattention, or criminal indifference to the patient's safety; and this may arise from his gross ignorance of the science of medicine or surgery and of the effect of the remedies employed, through his gross negligence in the application and selection of remedies and in his lack of proper skill in the use of instruments, or through his failure to give proper instructions to the patient or his attendants as to the use of the medicines. But where the person treating the case does nothing that a skillful person might not do, and death results merely from an error of judgment on his part, or an inadvertent mistake, he is not criminally liable.

The criminal liability of a physician for the death of his patient brought about by his gross negligence, carelessness, or ignorance, may be established on an indictment or information predicated on the general statute defining manslaughter. See—

tion 2392 of the Revised Statutes of Florida of 1892 providing as follows: "If any physician, while in a state of intoxication, shall, without a design to effect death, administer any poison, drug or medicine, or do any other act to another person which shall produce the death of such other, he shall be deemed guilty of manslaughter," does not furnish the only exclusive case where a physician can be held criminally liable for the unintended death of his patient brought about by his gross negligence or ignorance. Nor does said section render the provisions of the general manslaughter statute inapplicable to cases of death unintentionally produced by physicians through gross negligence or ignorance, where there is no question of the sobriety or intoxication of such physician; but the provisions of said Section 2392 were intended as an addendum to the provisions of the general manslaughter statute, in cases of unintentional death at the hands of physicians, to provide for cases that might not be covered by the general statute.

Where an information charges a physician with negligently pulling out the "intestines" of a patient, whereby her death was produced, it is competent at the trial to prove under such charge that the larger omentum, the mesentery, or any other organ having its place in the abdominal cavity, was pulled out or removed. The word "intestines," when used in an information or indictment, must be given its broadest popular and most comprehensive sense, as denoting everything on the inside, within, internal, inward as opposed to external, and, when applied to the human anatomy, includes the bowels, entrails, viscera, enteron, with all of their annexes and appendages; indeed, everything contained in the abdominal cavity.

 6. Ruptured Ectopic Pregnancy Complicated with Appendicitis. B. F. Stevens, El Paso, Texas.
2. **Tuberculosis of Thoracic Duct.**—Longcope reports 30 cases of tuberculosis in which especial attention was paid to a study of the thoracic duct as a possible point of origin for the generalized process. Of these 30 cases, 19 were typical instances of generalized acute miliary tuberculosis, in which minute tubercles were scattered in enormous numbers through most of the organs of the body. When histories could be obtained, it was found that the course of the disease was rapid, lasting usually from two to twelve weeks. The thoracic duct in 14 of the 19 cases showed a more or less extensive tuberculosis, usually with caseous nodules, while in one instance, though there was no tuberculosis of the wall of the vessel, many tubercle bacilli were found in smears from the duct lymph. In one of the four remaining cases in which the duct was normal there was a primary tuberculosis of the epididymis and testicle, with organized thrombi in the vesical veins, containing caseous masses and tubercles. In eight instances the generalizing process was subacute or chronic. Large tubercles or caseous masses were scattered in small numbers through the various organs, while during life the course of the disease was protracted, lasting from three to nine months. In only two of these cases was there a tuberculosis of the thoracic duct. In both instances the tubercles were small and occurred sparingly, but in one a few tubercle bacilli were found in smears from the fluid of the duct. Finally, in three instances, the tuberculosis was of a chronic type and confined to the lungs and peritoneum. In all of these cases the thoracic duct was normal. Of the 27 cases of tuberculosis in which the process was more or less generalized, 17, or almost 63 per cent., showed tuberculosis of the thoracic duct, or, as in one instance, tubercle bacilli in

the lymph from the duct without lesions of its walls. Of the acute cases in over 79 per cent. the duct was affected or contained tubercle bacilli. The type of lesion in the duct varied considerably. Sometimes there was a single large caseous nodule usually near the receptaculum or about the arch of the aorta, with small tubercles over the intima of the vessel above and below it; sometimes several caseous nodules were scattered through the duct, while occasionally the walls of the lymphatic were simply seeded with small tubercles. In every instance the lymph nodes of the mesentery, retroperitoneum, posterior mediastinum, or bronchial regions were the seat of a chronic tuberculosis. At times several groups of glands were affected, but more often only one group, and rarely only one or two glands. Often the lesion in the duct appeared almost as old as that in the neighboring lymph nodes and was in close association with it, though a direct extension of the process from the gland to the wall of the duct was never seen. In at least two cases caseations of a small group of lymph nodes and of the thoracic duct wall were the only foci of chronic disease which could be found in the body. From the study of these cases Longcope concludes that tuberculosis of the thoracic duct is of great frequency in cases of generalized tuberculosis. He believes that the lesions in the duct from which tubercle bacilli are swept in great numbers through the lymph to the general circulation form the starting point for the generalized acute process.

4. **Priapism in Leukemia.**—Gunkel reports a case in which this symptom occurred. He believes that the changes which take place in the corpuscular elements in leukemic blood conduce to this condition, and that the consequent leucocytosis produces certain changes in the blood vessels that are concerned in the mechanism of an erection.

5. **Fatal Hematemesis in Chronic Gastric Ulcer.**—Murdoch reports the case of a man aged 40, who, after living on liquids for two months, was able to take solid food without discomfort. He had good health for two years after this time, then began having pain two or three hours after meals, which was relieved by sodium bicarbonate. Six years later he began to have severe pain which was not relieved by sodium bicarbonate. The pain was accompanied by vomiting, then by hematemesis, which continued at intervals till his death, four months afterward. The bleeding could not be stopped by any of the measures usually employed for this purpose. Operation was urged but refused. The autopsy showed an ulcer 3½ by 2½ inches, situated on the posterior wall of the stomach. The base of the ulcer was formed by the pancreas, to which the stomach was firmly adherent.

 13. Redism, Its Known Medical Value. M. Metzelsbaum, Cleveland, Ohio.
7. **Rupture of Esophagus from External Traumatism.**—Lomax says that there has been, up to this time, but one case on record which can be properly included under rupture from external traumatism. The author's case, which is the second to be reported, was that of a woman aged 44, whose body was forcibly compressed in an elevator accident. She was not rendered unconscious and did not complain of great pain. Death occurred eleven hours later, after a rather sudden onset of the symptoms of collapse, and the autopsy revealed a rupture of the esophagus, close above the diaphragm, with escape of stomach contents into the left pleural cavity. There were in addition, multiple fractures of the pelvis.
8. **Acute Yellow Atrophy of Liver Following Eclampsia.**—Royster and Grandy describe a case and review the modern theories regarding the relationship of these diseases. They sum up their own belief as to their identity as follows:

1. A toxæmia is always the primary condition, but it may be severe enough only to produce the early symptoms—headache, lassitude, disturbances of vision, and a diminished excretion of urine and urea, with possible edema and albuminuria. In a few cases shown, the pathologic findings being the same as in eclampsia. 2. In eclampsia (the second stage) the toxæmia has become severe enough to interfere greatly with the functions of the liver and kidneys, and to produce the nervous irritation, made evident by the convulsions and coma. The severe poisoning here produces grave lesions in various organs, and often causes death. 3. In acute atrophy of the liver the changes have progressed still further and have practically destroyed this organ, and have added to the convulsions (which, however, do not necessarily occur) a deepening coma, an increasing jaundice, vomiting, and often purging, with blood in the stools, followed practically always by death.

9. **Selective Absorption by Cell.**—Waugh argues that the individual cell has a selective power and is able, therefore, also to control drug absorption. If a drug is administered, those cells needing the particular properties bestowed by the remedy will take it up, whereas the others that are not likely to be benefited by it do not absorb it. He concludes that it may often be advantageous to give several remedies together that are apparently antagonistic in action, with the expectation that the proper cells only will be influenced.

11. **Nailing Head of Humerus for Fracture of Surgical Neck.**—Haubold describes a procedure successfully employed in a case in which the displacement could not be overcome by ordinary means. Langenbeck's anterior incision was made, the deltoid separated from the pectoralis major, and the fracture exposed. There had been much subcutaneous hemorrhage and the upper end of the lower fragment was somewhat comminuted; the loose fragments were removed. The fragments were brought into apposition with considerable difficulty, and only by forcibly prying the lower fragment outward with the aid of a periosteal elevator. With the fragments held in place, a small skin incision was made at the outer edge of the acromion process and a four-inch steel nickel-plated nail was driven through the head of the bone and onward into the shaft, thus firmly fixing the fragments in place. About three-fourths of an inch of the nail, with its head, was permitted to protrude from the skin. At the end of a week a plaster-of-Paris dressing was applied and four weeks later the nail was removed. Recovery of function was perfect.

12. **Sutures and Their Preparation.**—Watters commends highly a method of sterilization of catgut devised by W. F. Wesselhoef. This consists in placing the separate strands in a small envelope which is enclosed in a larger one. The envelopes are dried and packed in a small brass case which is filled to a definite point with alcohol and is closed hermetically with screw bolts. The case is then immersed in boiling water for an hour. This raises the temperature of the contents to 212 degrees and develops a pressure of 25 pounds to the square inch, thus insuring thorough impregnation of the catgut with the alcohol. The envelopes dry in a short time on removal from the alcohol. The advantages of the method are that it is simple and inexpensive to carry out, while both practical experience and the author's culture experiments prove that absolute sterility is obtained. Fractional sterilization is illusory in dealing with catgut.

16. **Puerperal Septicæmia.** E. H. Stevens, Cambridge, Mass.

15. **Fracture of Superior Maxilla.** The variety of fracture discussed by Lofthrop is that generally classed as a fracture of the malar bone involving either its body or the zygomatic arch. Lofthrop treats these cases as follows: The cheek on the affected side is raised and drawn to one side so as to expose the canine fossa. A horizontal incision about three-quarters of an inch long is made along the line of junction of the mucous membrane of the alveolus and the cheek in the uppermost portion of the canine fossa. The incision is posterior to the canine ridge, and is at the highest point of the vestibule of the mouth. The incision is then carried down directly to the bone and the soft parts are slightly freed by means of a periosteum elevator. The director is now pushed through the fissure, or, if

none be detected, through the intact bone into the antrum of Highmore. Guided by the groove of the director, the operator may pass larger instruments into the antrum, tending meanwhile to force the fragments upward and forward. The opening should be made sufficiently large to pass a No. 24 French sound. With elevators of suitable size and shape the depressed portion of the anterior wall of the maxilla may be elevated. Then a sound is introduced and its tip carried to the apex of the antrum, that is, directly opposite the malar bone. The head should be held erect and firm by assistants. Both hands of the operator should be placed on the sound, one being about half-way down and resting on the side of the face in order to give support and steadiness. Gradual increase in pressure is then exerted on the sound, the force being directed in such a manner as to tend to replace the malar bone in its normal position. As it resumes its normal position the asymmetry will be seen to disappear. By means of the sound and the other elevators all fragments may be replaced. The finger placed on the skin over the malar bone and over the region of the anterior wall of the maxilla will serve for a guide as to the completeness of the reposition of fragments. Finally, a rather broad instrument is introduced through the opening into the antrum with its tip directed toward the malar so as to hold this bone in position. Then long and very narrow strips of iodoform gauze and sterile gauze should be introduced carefully so as to pack the antrum. These strips should fill up first the malar end of the antrum, gradually approaching its nasal surface. Care must be taken not to push back the fragments of the maxilla and also not to force gauze in between the maxillary surface and the cheek. The ends of all of these narrow strips should be left just protruding at the incision in the vestibule of the mouth. When properly packed the position of all fragments may be maintained. No external dressing should be applied.

26. **Aphasia, Hemiparesis and Hemianesthesia in Migraine.** S. E. Jelliffe, New York.

17. **Prevention of Cistricities Following Breast Operations.**—According to Murphy, the best results are obtained by making the incision high up on the chest and rectangular; the apex of the incision should be just beneath the acromion process, the inner limit parallel to the fibers of the pectoral and the outer parallel to the long axis of the humerus. The incision permits of removal or division of both of the pectorals and allows the greatest latitude for axillary dissection. Next to the rectangular, the sinuous incision favored by Rodman causes the least disturbance from contraction. If the skin is involved, the line of incision must be accommodated to the extent of excision of the skin demanded by the pathologic condition, and semicircular flaps rolled from the chest, back or shoulder should be so formed as to cover the denuded area. These, however, should never be united so as to form a straight scar at the anterior axillary line. Murphy says that the best muscle to cover the important structures of the axilla is the lower part of the pectoralis major. Its aponeurosis should be removed with the breast, as the aponeurosis, and not the muscle, carries the lymphatics, in which metastasis occurs. The muscle is then cut from its costal attachments for a width of from 2 to 2½ inches, well toward the sternal margin, and split outward parallel to its fibers, allowing the humeral attachment to remain. The remaining portion of the pectoralis major, its fascia, the pectoralis minor and its fascia, may or may not be removed, depending on the operator's predilection

in this matter. When the dissection of the axilla is complete the pectoral flap is drawn across the nerve artery and vein, and fixed at the apex of the axilla, covering the anterior and inferior surface of these structures. Three or four stitches are sufficient for the purpose. Two or three additional sutures may be made attaching the flap to the latissimus or subscapularis. If the latissimus is used it should be divided well down, 2 inches of its margin and fatty tissue freed and the muscle split upward toward the humeral attachment, the flap drawn forward and upward and attached in the same manner as the pectoralis, to cover the axillary structures. The skin flaps are then placed in position in the usual way. After these procedures there is a fullness in the axilla, but this rapidly subsides as the muscle atrophies. When the wound is closed the arm is dressed at right angles to the body. It is held in this position by an axillary cast extending over the side of the chest and out over the arm to the elbow. The position is not uncomfortable. The cast immobilizes the structure during the process of repair. It can be removed at the end of ten days, when the stitches are taken out. Murphy insists that there should be a perfect approximation of all the axillary surfaces when the operation is complete and the arm is dressed and placed in position. The article is illustrated.

22. New Operation for Chronic Endotrachelitis.—In connection with this operation Craig has devised three instruments. (1) a cervical forceps designed to grasp the anterior aspect of the portio vaginalis as near as possible to, but not into, the external os; (2) an external os dilator, and (3) a curette, the edge of which is obtained by beveling from above downward and inward, making the blade cut as the curette is withdrawn. The patient is placed in the Sims position. For several days prior to operation the patient uses three two-quant 1 to 5,000 formalin douches, moderately hot, so as to secure thorough asepsis. It is not necessary to scrub or to shave the vulva. The vagina is thoroughly scrubbed with a pledget of sterile cotton saturated with a strongly alkaline solution, and this is immediately followed by a scrubbing with 1 to 5,000 formalin, or any equally efficient germicidal solution. The os is dilated and the anterior outer aspect of the portio vaginalis is grasped with the forceps as near as possible to the external os. The grasp should be deep and firm enough to furnish good counter-pressure without danger of tearing out. Care should be taken not to have the teeth penetrate to the lumen of the canal. The tip of the dilator is then introduced through the external os and against the counter-pressure of the forceps is forced home until the shoulder is in contact with the external os. Care must at all times be taken to avoid unnecessary downward traction, as this puts unnecessary strain on the uterine ligaments and favors subsequent malpositions of both uterus and appendages. The curettement of the cervical canal must be so thorough as completely to remove the cervical mucosa giving the familiar grating sensation felt when the musculature is reached. In proper cases no particular care is needed to guard against passing the internal os. The curettement is concluded by a few rotations of the curette on its long axis while it is gently pressed against the resistance offered by the internal os in order to remove the tissues immediately subjacent. Finally the cervical canal now denuded is antiseptized by the application of iodized phenol to its entire surface, the vaginal vault is filled with powdered boric acid, and a 33 per cent. ichthyol and glycerin strip is laid against the os internum and about the portio vaginalis. Diseases of the tubes and ovaries contraindicating traction and of such a nature as to make any collateral treatment only partially successful should constitute a contraindication to this form of treatment except as an immediate preliminary to the radical treatment of the associated lesions.

31. Xanthelasma and Chronic Jaundice.—The three cases reported by Futcher all occurred in women, their respective ages being 39 (two), and 42 years. The duration of the jaundice before the xanthomata appeared was eight months, eight years and one and one-half years. The cause of the jaundice was gallstones of the common duct in two cases, in one of which there was also biliary hypertrophic cirrhosis of the liver, and in the third case hypertrophic cirrhosis of the liver alone. In all three cases the eyelids were involved; in one the eyelids only. In the other two there were lesions on the extremities and to a less degree on the trunk. In two cases the xanthomata appeared on the hands first; in the third on the eyelids. The xanthomata were chiefly in the form of plaques in all the cases. There were a few nodular xanthomata in two cases. The distribution was strikingly symmetrical. In one case there were xanthomata on the gums, and in another histologic examination of the bile ducts showed that xanthomata of the mucous membranes of the ducts were present. At all events the histologic picture showed cells identical with the "xanthoma cells" of the lesions in the skin. In one case there was a spontaneous disappearance of the xanthomata four and one-half years after the onset of the disease, and about four years after the gallstones were removed at operation. Two of the patients were operated on, and one came to autopsy, so that the causes of the jaundice were definitely ascertained. Futcher says that four-fifths of the cases of xanthoma multiplex in adults occur in chronic jaundice. In these cases men and women are about equally affected, with possibly a slightly greater frequency in the latter. The hepatic conditions causing the jaundice have been found to be gallstones, stricture of the bile ducts, atrophic and hypertrophic cirrhosis of the liver, hydatids and cancer. In addition to the skin, the tendons and mucous membranes may occasionally be involved. The onset is said to be most frequently on the eyelids. The xanthomata accompanying jaundice are believed to be directly traceable to the latter or to some associated toxic substance circulating in the blood. Symmetry in distribution is often striking, and the tendency to develop in the folds and creases of the joints is a remarkable feature. The views as to the actual nature and sequence of tissue changes in the lesions vary much. Once they develop they rarely disappear. Spontaneous involution is rare. No treatment other than surgical, in suitable cases, is of any avail. The indications are to relieve the underlying process if possible.

38. Herpes in Pneumonia and Cerebrospinal Meningitis.—Howard believes that the cases reported by him furnish additional proof to support the position that the ordinary herpes zoster, as well as the herpes of pneumonia and cerebrospinal

meningitis, is a pathologic condition dependent on definite lesions of certain sensory ganglia, which may be caused by a variety of agents acting in different ways. The herpes is dependent on the ganglionic lesions, and apparently does not vary with the causes of the latter, whether they are due to embolism, thrombosis, hemorrhage, invasion by tumors, micro-organisms and their toxins, or to other poisons. The ganglionic changes in the cases of herpes complicating pneumonia and cerebrospinal meningitis studied by Howard were identical with those described by Head and Campbell as occurring in their acute cases of so-called spontaneous herpes zoster. In the herpes of meningitis the ganglion changes probably are commonly due to an extension of the inflammatory process along the nerve roots to the ganglia. In pneumonia the *matrices morbi* are apparently brought to the ganglia by the circulation.

41. Case of Myoclonus Multiplex.—Hecht's patient, a man aged 28, was a prize-fighter by profession. His family history was negative, except that the father died of a cancer of the lip at 52. The personal history also was negative, except that the patient had had three attacks of gonorrhea. His personal habits had been very bad. He had used liquor excessively. Following a severe indulgence in liquor he noticed a twitching of the abdominal muscles which gradually increased in severity and also became more generalized. There has never been loss of consciousness, frothing, biting of the tongue, or tonic rigidity. The man has never had anything resembling an epileptic fit. The twitches are now so severe that locomotion is almost impossible. The acts of dressing and undressing are most tedious and cumbersome. The characteristic twitching is noticeable in all the muscles. The speech of the patient is too interrupted and explosive to be understandable. Deglutition is much interfered with. Myotatic irritability is increased. Sensation is nowhere disturbed. Whisky and cloral alone allayed the mild spasms.

42. Infectious Arthritis.—Fayerweather reports 3 cases of infectious arthritis in which the bacteriologic findings were positive, and a fourth case of typical acute articular rheumatism. It was impossible to identify any of the organisms found in the affected joints with previously described germs.

43. Fatal Case of Stokes-Adams Disease.—In the case described by Stengel there was found at the autopsy a moderate grade of general arteriosclerosis. The heart was hypertrophied, the walls of the left ventricle being especially involved. The heart muscle was normal in appearance in all parts, except where an endocardial lesion affected a small area at the upper part of the interventricular septum. The root of the aorta was slightly atheromatous, and the openings of both coronary arteries were involved. The coronary arteries themselves were distinctly thickened, but in no place calcareous or stenotic. The aortic leaflets were slightly diseased, but not calcareous. The valves seemed to be competent. The lesion of importance was one on the anterior mitral leaflet toward its base and the aortic edge. This was a patch of atheromatous character, sclerotic and white, and it extended to the endocardium exactly over the bundle of His, where this band passes from the ventricle to the auricle. Viewed from the side of the right ventricle, the specimen did not show any evidence of penetration of the sclerotic process, but on the left ventricular side it was evident that the bundle of His was involved in the area of disease. The histologic findings in the case will be published later.

50. A New Hemorrhoidal Clamp. The body of the instrument devised by McLean is not unlike some clamps already in

use. The blades are curved longitudinally, with one inner margin grooved and the other ridged. On the concave surface toward the inner margin of each blade are a number of grooves sloping from without inward, the deepest portion of the groove dipping down two-thirds of the thickness of the blade. When the instrument is closed the grooves of opposite blades come together so as to form a continuous depression. These grooves are about one-eighth of an inch apart and one-eighth of an inch in width. The hemorrhoid is drawn into prominence by forceps or tenacula and the clamp placed at the desired portion of its base and closed. The pile is then removed with curved scissors or knife, following the concave surface of the clamp. The margins of mucous membrane are now stitched together by passing a well-curved needle, with catgut ligature, through each groove. This suture may be continuous or interrupted. If but a few stitches are required the ends of the continuous suture can be brought together and tied as soon as the clamp is removed. These stitches control all hemorrhage, and bring the margins of the wound in close apposition. There is a very small margin of tissue compressed by the clamp and little sloughing follows. McLean says that there is much less pain following this method than when the ligature or cautery is used. The result, he claims, is ideal, as it leaves the tissues in their normal position, without any fear of hemorrhage following, or of cicatrices forming later. This instrument can be used satisfactory for the ligation of any pedicle.

52. Pica.—Schadle reports the case of a sugar eater, aged 43 years, who consulted him in reference to a spasmodic affection of the throat. At certain intervals the patient suffered from these attacks for a period of three years. The paroxysms were marked by periodicity, usually manifesting themselves during the menstrual epoch. The attacks were often induced by foreign substances coming in contact with the laryngeal structures. The mucous membrane of the buccal and faucial cavities was dry, smooth and markedly red. In fact, the color and general aspect of the tongue, mouth, pharynx and larynx suggested the characteristic local appearances of diabetes. The larynx was also hyperesthetic. Local applications of chlorid of zinc to the larynx were followed by relief. Prior to twelve years ago the patient had an abnormal appetite for acids, and to gratify this desire she indulged in the free use of lemons and sour pickles. In order to get rid of this habit she sought medical advice, and was given a prescription for a bitter concoction which she claims made her very ill. After recovering from the illness this produced a ravenous appetite for sweets developed, which perverted function she indulged by eating large quantities of sugar. White, granulated sugar she preferred. The habit of eating sugar grew stronger until she finally found that it was impossible to get along without it. By and by natural food was excluded from the diet to the extent that she practically subsisted and depended on sugar. This practice was kept up for twelve years without producing any apparent damage to the system. No fixed time of the day was established for eating the sugar. She ate it almost continuously from the time of rising in the morning until retiring in the evening. The patient consumed on an average about four pounds daily, or, relatively speaking, three-fourths of a ton in a year.

56. Sepsis in a Newborn Infant.—In Jacob's case nothing was noted until the fourth day. Then heavy uric acid infar-

tions were discharged, which lasted until the eighth day, recommencing on the ninth and lasting till the tenth day. A circumcision was performed on the eighth day, with no accident. Purpuric spots of a small size were seen on the extremities on the ninth day. Hematuria appeared on the twelfth day and continued. The baby died on the seventeenth day. The autopsy disclosed a left kidney enlarged to almost twice its natural size, dislodged downward, capsule penetrated with blood, and some clots between capsule and kidney. The upper part of the kidney formed a black, almost uniform looking mass. The right kidney was similarly changed, but to a far less degree. The bacterial cause of the sepsis in this case was not known, although Jacobi thinks that infection may have occurred through the umbilical stump, the cord not having fallen off before the fourteenth day. The dressing employed was borie acid, which he thinks is not a sufficient antiseptic to be applied as a protection to a vulnerable surface like that of the navel.

61. Soluble Preparations of Mercury in Syphilis.—Klotz favors the administration by mouth of soluble preparations of mercury in the treatment of syphilis. He prescribes 15 gr. of the bichlorid dissolved in 100 grams of water. One teaspoonful of this mixture is to be taken three times a day, from one-eighth to one-fifth of a grain of the bichlorid at each dose. As a rule he does not add syrups or aromatics, as these might favor decomposition of the solution; but the patients are always advised to take the medicine diluted with water or milk some time after meals. Klotz does not recommend this method as the exclusive treatment of syphilis, but employs the other methods as well, particularly in hospital practice.

66. Diplobacillus of Morax and Axenfeld.—Gifford claims that this germ has not received the attention in America which it deserves. One reason for this, he says, is the insignificant character of the symptoms which, in the majority of cases, it produces. In the typical diplobacillus catarrh there is only a moderate redness about the inner angle, while the subjective symptoms consist chiefly in an itching which many patients bear with composure. The discharge is so scanty that the lids are not stuck together in the morning, and the bacteriologist is not especially tempted to investigate it. In fact, the appearances in the majority of cases hardly suggest a specific infection of the conjunctiva, but rather a casual irritation. In quite a number of patients the eyes do not look inflamed at all, and the discharge is not in excess of that which one often sees in practically normal eyes; none at all being seen on a casual inspection, but on carefully examining the innermost angle of the palpebral fissure a speck of mucus no bigger than a pin's head can be discovered which is often swarming with the diplobacilli. The subjective symptoms in such cases are often quite misleading, the sole complaint of some patients being that they can not read at night. There are two forms of the disease which without the aid of the microscope must fre-

quently be called trachoma. One of these is the acute form, with rather profuse secretion and marked swelling and roughness of the retro-tarsal folds; and a chronic form, in which the patient presents himself with a set of symptoms such that until one has been put on his guard, a snap diagnosis of chronic trachoma is almost sure to be made on first examination. The eyes are red and watery, half-dry secretions cover the edges of the lids, and retro-tarsal folds are moderately rough and red. The tarsi, however, are but slightly affected. This form occurs chiefly among the poorer classes of Russian Jews and is apparently the product of dirt, neglect and slight eversion or closure of the lower tear points. In the treatment of this affection Gifford employs chlorid of zinc, one grain to the ounce. In the more obstinate cases he uses a 2 per cent. solution.

- 6 *Cause of Detachment of the Retina. J. A. Craig.

1. Fashions in Surgery.—Thomas favors the wearing by operators of a sterilized over-all, made long enough to prevent the surgeon's hands from coming in contact with his nether garments. The sleeves should be long enough to cover the forearm down to the wrist. The over-all possesses a bib with which the surgeon can cover his mouth and nostrils by slipping the tapes around the ears and tying them under the chin. The bib is necessary for a surgeon who has a long, flowing beard or has a cold, and also to those who can not keep their mouths closed during operations, or who perspire freely. A sterilized cap also is essential, he says, for surgeons who wear long hair, or who are short-sighted, or who go in for motoring. A surgeon, in order to be *de rigueur*, should wear permeable thread gloves which are sufficient protection against a successful invasion by germs of the field of operation in aseptic or clean cases. Thomas also urges that the surgeon protect himself against personal contamination during the examination of patients.

4. Puerperal Eclampsia.—Dunlop analyzes 50 cases. Edema was present in 30 cases, but was not a criterion of the imminence of convulsions. One of the most important, because one of the most suggestive and unequivocal, of the prodromal symptoms is pain in the epigastrium. The pain is at first slight, or there may be only a sense of discomfort; but when this symptom is well-marked, it becomes later so intense that the woman is rendered prostrate and is forced to cry out. It may be associated with pain in other regions of the abdomen or in the loins, and may be accompanied by vomiting or difficulty and oppression in breathing. These concomitants are most frequent when the pain has become intense and continuous, and betoken the imminence of convulsions. In all cases a very rapid involution of the uterus took place. In Dunlop's eight personal cases the delivery of the woman stopped the convulsions in one case; in two cases it mitigated the severity of the convulsions, and in four cases had either no effect or a bad one. Of the remaining 42 cases, two patients died undelivered; even occurred in the puerperium; in twenty-one cases delivery had no effect; in four the convulsions ceased at delivery; in three the convulsions were mitigated after delivery, and in five they were more severe and frequent after than before delivery.

6. Detachment of Retina.—Craig reports a case in which, after all other measures failed, he evacuated the subretinal fluid by scleral puncture, using for the operation an ordinary iridectomy knife. The subretinal fluid came away freely, and examination of the eye immediately afterward with the ophthalmoscope showed the originally grey detached retina back in position with its pink color restored, the subjective sensation of a grey veil simultaneously disappearing. He followed the puncture by another subconjunctival injection and bandaged the eye firmly with a pressure bandage. In four days the retina again became detached, with return of the subjective phenomena, and he decided again to puncture and, in addition, to apply the galvano-cautery over the seat of operation, with the intention of setting up enough adhesive inflammations of the parts to fasten down the retina. This was done on the twelfth day from the institution of the treatment, and again the immediate effect was completely successful. For eight days after this the retina remained in position, and again the detachment recurred. The former results of the operation had been favorable enough to justify a repetition of the procedure, and this was again done, now near the end of the fourth week from the beginning of the treatment. On this occasion he dissected back a flap of conjunctiva in order to allow the puncture to be made as far back as possible, and the cautery was energetically used. After this no signs of detachment returned. As a precautionary measure, however, he thought it advisable again to apply the cautery at the end of a week in order to cause further inflammatory adhesions. On testing subjectively it was now found that there was a relative color scotoma in that portion of the field corresponding to the seat of the detachment, that is to say, that color sensations as determined by a blue test object were, according to the degree of illumination, confused or quite lost over this area, although the object itself could be seen. Examination of the fundus showed slight opacity and one or two punctate deposits of exudate in the affected portion of the retina. The normal pinky appearance, however, was quite restored. More peripherally the position of the punctures and cauterizations could be easily seen as a deeply-scarred and pigmented surface. The dorsal position was maintained for ten days further and then the patient was allowed to go home. Three weeks later the condition was still found quite satisfactory, central vision (corrected) being 6/6, and the only visual defect being a relative color scotoma over an area of the field extending from the thirtieth to the sixtieth degree in the lower half. On November 16 this scotoma had so improved that the patient could appreciate colors, but blue appeared darker. The patient was last seen by Craig in April, 1905—that is, twenty months after the termination of treatment. Vision was still 6/6, and no sign of detachment could be detected.

- 12 *Prevention of Appendicitis. W. J. Tyson.
- 13 Case of Abdominal Tuberculosis. R. W. Philip.
- 14 *Ventral Fixation of the Uterus by a New Method. W. G. Richardson.

8. Chronic Pancreatitis.—Robson's case is interesting because it was unaccompanied by gallstones and was apparently due to an extension of catarrh from the duodenum up the pancreatic duct. The interstitial changes only involved the head of the pancreas.

9. Tuberculous Glands of Mesentery.—Corner cites 5 cases. The first case, in a man, aged 41, illustrates the co-existence of atrophic appendix and a large caseous gland in the mesentery of the small intestine. The gland, about the size of a large walnut, was incised and the caseous material removed. The walls were everted and were then invaginated with silk stitches and the cavity left by the removal of the caseous matter was obliterated. The patient recovered. The second patient had many tuberculous glands in the mesentery compli-

cated by an active appendicitis. The appendix was removed, but the glands were not touched. The third case was that of a boy with whom the diagnosis rested between tuberculous glands in the mesentery and sarcoma. The glands were removed and the patient made a perfect recovery. The fourth case was of particular interest on account of the occurrence of colicky pains. These and the looseness of the bowels suggested a tuberculous enteritis. Although the disease was very extensive, the glands were removed and the patient was very much improved, but still had occasional and unexplained attacks of diarrhoea. The fifth case gave every evidence of being one of general military tuberculosis; nevertheless the mesenteric glands were shelled out and everted. The patient improved a little, but after a few days the meningitic symptoms became more pronounced. The patient died in a few weeks, and the necropsy revealed a general military tuberculosis.

12. **Prevention of Appendicitis.**—Tyson is of the opinion that careful regulation of the food, both as to quantity and quality, the manner of eating, the avoidance of constipation and a correct method of stooling are important factors in the prevention of appendicitis. He believes that the old-fashioned and natural method of defecating on the ground, with the thighs flexed on the abdominal walls, so that in straining the inguinal and femoral canals are practically closed, is made more conducive to the thorough emptying of the bowel and, therefore, less likely for obnoxious and poisonous materials to be left behind. The practice of kneeling down, bringing the buttocks in contact with the heels, and the anterior chest wall in contact with the thighs, three or four times every morning, is a good and beneficial exercise, which he has practiced for some time past and which he recommends to others.

13. **Raw Meat in Tuberculosis.**—Philip discusses his experience with the use of raw meat in the treatment of pulmonary tuberculosis. His results have been exceedingly satisfactory.

14. **Ventral Fixation of Uterus.**—In order to avoid certain defects in the ordinary procedure of ventral fixation of the uterus, Richardson devised a new method which has yielded excellent results in 12 cases. It is intended for the relief of patients suffering from severe forms of prolapse of the uterus, with cystocele and rectocele, with or without rupture of the perineum. The method is free from the immediate danger of hemorrhage and from the remote danger of long bands of adhesions, and it secures the uterus in its new position in such a way that it can not possibly drop back. The operation is described as follows:

1. Open the abdomen in the middle line from the pubes to the umbilicus.
2. Retract the left side of the wound and take hold of the left round ligament of the uterus, then draw on it until it is tense between the point laid and the inguinal canal. Catch it with two clip forceps as near to the inguinal attachment as can conveniently be done and divide it between the clips. Ligate the distal end and remove that clip, dropping the stump. Retain the clip on the proximal divided end.
3. Repeat this on the right side.
4. By means of the two clips on the proximal divided ends of the round ligaments draw the uterus up toward the abdominal wall. Some tension will thus be made on the peritoneal attachments of the round ligaments and, as a rule, the peritoneum will stretch sufficiently to allow the uterus to come up into the wound, even, in some cases, as high up as the umbilicus, but it may be necessary to make a few cuts in the saccus in the folds of the peritoneal attachments, in which case care must be taken not to cut right up into what may be called the "axilla" of the round ligaments lest any vessels be injured. Lift the uterus by its round ligaments as high up in the abdomen as it will reach without undue tension and with the eye mark the position. In some of the cases of complete procidentia the uterus was purposely left outside the vulva before the abdomen was opened and it came up without any difficulty when drawn on by the round ligaments.
5. At the place to which the fundus of the uterus reaches catch hold of the skin and superficial fascia on the left side of the wound and draw on them at the same time separating them from the abdominal aponeurosis by thrusting in the handle of a scalpel as far as the outer edge of the rectus abdominis muscle. Withdraw the handle of the scalpel and pass a pair of clip forceps into the track thus made as far as a point one and a half inches from the middle line incision and then thrust the clip forceps through the aponeurosis, the rectus muscle, and the peritoneum into the peritoneal cavity; with the clip catch hold of the end of the left round ligament and draw it through the abdominal wall, keeping the clip attached.
6. Repeat this on the right side and then by dragging on both round ligaments the anterior surface of the uterus will be seen to come up and to lie against the anterior abdominal wall.
7. Whilst an assistant keeps up traction on both round ligaments and so retains the uterus in its new position sew up all the abdominal wound, except the superficial fascia and the skin, in layers with catgut. Let one or two of the sutures of the peritoneal layer be passed through the peritoneal coat of the uterus and thus occlude

the passage between the abdominal wall and the uterus, through which it is conceivable that a loop of small intestine might and is which it is conceivable that a loop of small intestine might and is which it is conceivable that a loop of small intestine might and is

8. Lay the left round ligament at right angles over the front of the aponeurosis and across the middle line as far as the point at which the right round ligament emerges. Ligate the left round ligament at that point and sew the ends of the ligature to sew the ligament to the aponeurosis there. Cut off any redundant ligament.
9. Do the same with the right round ligament and the two ligaments will then lie side by side across the front of the aponeurosis. Additional security is made if a few sutures attach the edges of the round ligaments to one another and also to the aponeurosis, but care must be taken to see that too much of each ligament is not included in each suture lest the blood supply beyond be diminished.
10. Suture the skin and the operation will be completed.

The method is said to possess the following advantages: 1. It is a simple operation in which there is a minimum amount of bleeding and shock. 2. It can be performed rapidly, a point of considerable importance in fat women. 3. There is no fear of hemorrhage from needle punctures of the uterus. 4. Patients have very little pain during the first few days as compared with those on whom the usual operation has been performed. They are able to be moved in bed more easily and, without dragging pain, can lie comfortably on either side. 5. There are no sutures to be removed. 6. There is no fear of the formation of long bands of adhesions. 7. The uterus is permanently held in excellent position.

32. Sero-prognosis of Tuberculous Pleurisy.—Courmont's research with 115 patients during the last seven years has confirmed, in his opinion, the hypothesis he advanced in 1898 that there is some connection between the agglutinating power of the pleural effusion in tuberculous pleurisy and the evolution of the disease. The mortality is about 25 per cent. of those individuals with agglutination and 75 per cent. among those whose pleural fluids fail to agglutinate. The proportion of recoveries is higher, the more pronounced the agglutinating faculty. Agglutination, he thinks, is a reaction of defense, or at least it parallels the defensive reactions of the organism. Its intensity is in inverse proportion to the gravity of the disease.

33. Septicemia from Autoinfection Treated with Hot Horse Serum. Jayle describes 2 cases of septicemia resulting from endogenous infection. A laparotomy was performed on one patient who had long had a chronic suppurative in the pelvis, complicated recently with intestinal obstruction. The laparotomy wound became gangrenous. Gangrene also developed in the second case; the patient was a young man with a traumatic retroperitoneal hematoma that had become infected from the intestines. The condition of each patient was very serious, and the same micro-organisms were found in the gangrenous wounds as had been cultivated from the fetid pus removed during the operation. There was almost total absence of leucocytes in the wounds. Recalling the claims made by Petit in regard to the leucocyte-attracting power of hot horse serum, Jayle dressed the wounds with this, and found its local effect absolutely perfect. The large gangrenous wound was cleansed with peroxid of hydrogen and then dressed with wicks soaked in 90 gm. of horse serum and two tubes of the desiccated serum. The serum was applied hot, morning and night, and by the fourth day there was no longer any fetid odor and recovery progressed rapidly. He adds, in conclusion, that patients with putrid septicemia generally die from heart failure; consequently it is of the utmost importance to sustain the heart. He used calcein (1 gm. in the twenty-four hours), camphorated oil (1 or 2 gm. of a 1 to 10 solution every three hours), ether and artificial serum. Not more than 1 or 1.5 liter of the artificial serum should be injected during the twenty-four hours. The defective permeability of the kidneys and the dilatation of the right heart should be the guide for these measures. If the heart is dilated, 100 gm. of blood should be withdrawn before injecting 500 gm. of the artificial serum. If the kidneys are not acting, he recommends an injection of picrocain.

34. Suprarenal Syndromes.—Bernard uses the term "hyper-epinephric" to designate excessive functioning of the suprarenal glands, while "hypoepinephric" indicates insufficient functioning. Each has its syndrome, and there is also the Addisonian syndrome. He describes them all in detail, emphasizing the conclusions from recent researches to the effect that excessive functioning is sometimes the origin of arterial hypertension, with its train of consequences. Josué found that repeated injections of adrenalin induced the development of atheromatous lesions in the aorta of animals. Vaquez also ascribes to excessive functioning of the suprarenals the transient arterial hypertension observed in the course of acute affections, such as lead colic and eclampsia, also the oscillating or unstable hypertension sometimes observed, and the permanent hypertension which accompanies chronic affections, such as interstitial nephritis or lead poisoning. This conception rests on two hypotheses, namely, that a series of phenomena attributed to other causes are, in reality, due to exaggerated arterial tension, and, further, that excessive functioning of the suprarenals is the cause of increased tension. Further research is needed in

this line. Defective functioning of the suprarenals causes a syndrome characterized by asthenia, arterial hypotension, and various nervous and digestive troubles. The latter are generally repeated vomiting, accompanied by obstinate constipation, or there may be a choleric form diarrhea, especially in children. This syndrome may appear in an acute, subacute or chronic form. The Addisonian syndrome includes (1) melanoderma and possibly certain painful and digestive phenomena, constituting the sympathetic syndrome; (2) the syndrome of suprarenal insufficiency in its chronic form, complicated by the syndrome of defective functioning of the suprarenals, and (3) general symptoms due to primary cause. In a later article he proposes to discuss the share of these syndromes in inflammation and tumor of the suprarenals and in syphilis and tuberculosis.

35. Myxedema and Sleeping Sickness.—Lorand ascribes sleeping sickness to the degeneration of the thyroid gland under the influence of the toxins of the trypanosoma.

Semaine Médicale, Paris.

58. (XXXV, No. 51.) *Les causes de la paralysie complète du nerf laryngé inférieur ou recurrent. E. Felix (Bucharest).

59. Causes of Paralysis of Inferior Laryngeal or Recurrent Nerve.—Felix reviews the long list of causes which may induce complete paralysis of the inferior or recurrent laryngeal nerve. The list is a long one, from affections of the heart and large vessels, tumors in the mediastinum, esophagus or thyroid gland to affections of the respiratory organs as local causes, also causes acting from a distance, such as affections of the brain or medulla. The list concludes with chemical or microbial intoxications as general causes. The most frequent causes, however, are, aneurism of the aorta and tracheo-bronchial adenopathies, which should always be suggested by the discovery of recurrent paralysis.

59. **Judgment of Infectious Processes by Determination of Chlorids.**—The findings in a case of puerperal sepsis and in two of pneumonia are tabulated, the daily record of the elimination of nitrogen, chlorids, volatile fat acids and the amount of urine, with the temperature. The volatile fatty acids, the authors state, increase enormously when a pneumonic exudate is being reabsorbed, also the amount of chlorids. The increase in the latter is also characteristic of reabsorption of edema, but the fatty acids do not increase in this case. Convalescence in pneumonia is indicated by the balance between the chlorids and nitrogen, showing that the organism does not retain a large proportion of the nitrogen to make up the deficit in the tissues, as in a long wasting disease. When the fatty acids return to the normal figure, it may be assumed that the reabsorption of the exudate is completed.

61. **Shape and Position of Stomach.**—Pontick asserts that the stomach lies perpendicularly in by far the larger majority of normal persons. In case of affections of the surrounding organs crowding on the stomach, it seeks the position which will interfere the least with its functions. This results in its assuming most remarkable positions in some cases, as it has a wide play in its normal range of movement.

66. **Sources of Error in Examining Stomach Contents.**—Boas thinks that the test breakfast is a much more reliable means of investigation than the test meal, for reasons which he enumerates. The original test breakfast is 1 roll (about 35 gm. in weight) and 400 gm. water or the same amount of tea without any addition, the stomach contents to be withdrawn exactly one hour afterward. The first test breakfast should be preceded by ascertaining whether or not the stomach is actually empty. Neglect of this preliminary examination is liable to nullify the results of the test. Unless the test breakfast is given in the morning as the first meal, the findings are also liable to be misleading. The variations in the secretions at different times must also be taken into account, especially those during menstruation, so that a single examination seldom affords a decisive oversight of the conditions. Another source of error is in the composition of the fasting stomach content in case of retention. It is wise in such cases to determine both qualitatively and quantitatively the proportions of lab and pepsin, as well as of hydrochloric acid. Pathologic lactic acid fermentation is generally accompanied by loss of these enzymes, and knowledge of this may explain dubious conditions. Another source of error is the presence of bile, blood, mucus or saliva in the stomach content. Quantitative determination of the hydrochloric acid is impossible under these circumstances, and qualitative tests are decisive only when they are positive. The reflow of bile into the stomach in case of deep stenosis of the duodenum has a marked influence on the acidity of the stomach content. Tests for gastro-succorrrhea are liable to be misleading, as the preliminary rinsing is apt to induce a reaction in the way of secretion, and as it is impossible to be sure that all the liquid introduced has been taken out. Determination of the acidity of stagnating stomach contents and also of the secretions in the fasting stomach is of little diagnostic value. Boas further argues that the presence of normal or increased hydrochloric acid, with only few remains of the test breakfast, is evidence that the motor function of the stomach is comparatively unimpaired, but, on the other hand, when the stomach is found still

more or less full, we have no right to conclude from this that the motor function is defective. This conclusion is justifiable when the proportion of hydrochloric acid is abnormally small, with as much as 150 or 200 c.c. of stomach content, unless it is evident that there are no remains of the food in the fluid. He doubts the practicability and reliability of the new methods of stomach testing that have been introduced, and regards the old Leube method as still superior. The only drawback is that two or even three examinations with the sound are necessary to obtain unmistakable results. If a better method should be discovered, it would be wise to combine it with the test breakfast, which has stood the test of time and experience and conforms to the customs of all civilized lands. It is free from the drawbacks of the test meal, especially the interference with the tests for "occult hemorrhage" by the presence of the beefsteak in the stomach.

70. **Renal Diabetes.**—Lépine relates experiments with dogs and clinical experience which confirm the existence of a toxic glycosuria (with phloridzin) of renal origin. He is inclined to believe that there may be also a nervous glycosuria due to some (vascular) renal process. The existence of a renal diabetes in man, according to Klemperer's theory, is not irrational, but no absolutely convincing cases have been reported to date. He has had several patients under observation for years in whom glycosuria alternated with phosphaturia.

73. **Typhoid Fever Plus Shot Wounds of Abdomen.**—The patient was a young woman who was shot in the abdomen, the injury requiring resection of the ileum for 98 cm. or about a yard. The course of the case showed that the injury had been received during the onset of typhoid fever. An epidemic of typhoid fever prevailing at the time was of an unusually severe type, but the disease was very mild in this case, possibly owing to the fact that the part of the bowel removed was exactly the part generally affected by the typhoid process.

74. **Nutrient Enemata.**—The experiences related by Strauss indicate that Wernitz's technic has superior advantages. The enema is given very slowly with large amounts of fluid under very slight pressure. The tube has a shoulder, which prevents its slipping out of the anus, and a stopcock which is turned so that only a drop at a time enters the rectum. A quart of the fluid is thus given in the course of an hour under pressure of about 27 cm. Fifty enemata were given in this way, and all were retained for three or four hours or longer, and more than half of the nourishment thus given was refund in the stools. Two patients received twelve and fourteen of these enemata in the course of a week without irritation of the rectum. His formula is 1 l. water, 25 gm. of an easily soluble albumin, 50 gm. grape sugar, 50 gm. cream and a little salt, with .2 gm. menthol or .5 gm. thymol or 1 gm. salicylic acid. His research on the precipitins after ingestion of albumin showed that there is no elimination in the urine of unpredigested albumin given in an enema.

75. **Family Gastro-succorrrhea.**—A mother and two sons, 16 and 18, respectively, began about the same time to present symptoms indicating gastro-succorrrhea, and the objective findings confirmed the diagnosis. No organic affection of the stomach could be detected in any of them.

76. **Is Arteriosclerosis a General Affection?**—Bäumler presents extensive arguments to sustain his view that the general affection observed in case of arteriosclerosis is secondary. The primary trouble, he thinks, is the disturbance in metabolism. At first it has nothing to do with arteriosclerosis, but is due mainly to nephritis of various origins. The consecutive disturbances in the circulation, he believes, are responsible for the arteriosclerosis.

77. **Anti-cholera Education of the Public.**—Meyer preaches the necessity for enlightening the public, but he distinctly warns against telling the layman things on which there is still a difference of opinion among scientists. Half-knowledge should be reserved for discussion in scientific circles, and the layman should be informed only in regard to useful things about which there can be no question. He quotes extensively from official and medical regulations during cholera epidemics in the early part of the last century.

78. **Fermentation Test for Sugar in Urine.**—Salkowski men-

tions a number of points which should be borne in mind in this test. The result of the test must be positive with sugar to .1 per cent. There must be no apparent positive effect in urine free from sugar. If the urine becomes ammoniacal at the close of the test it is a failure. Ammoniacal urine should be boiled before attempting the test. This is usually followed by an acid reaction. The fermentation test is not reliable with urine containing blood, pus, albumin or albumoses. Salkowski's technic consists in adding a scrap of compressed yeast (about .7 gm.) to 15 c.c. of urine in a conical glass, stirring gently and then pouring the fluid into a test tube, closing the outlet by pouring mercury into the bend, setting the tube aside for from twenty to twenty-two hours at a temperature not less than 30 or over 38 C.

79. **Treatment of Habitual Constipation.**—Jürgensen thinks that habitual constipation should be treated by hygienic measures, aiding Nature, rather than by drugs. If a purgative has to be given regularly it should be one that merely helps to empty the bowels without altering the consistency of the stools or causing by-effects of any kind. He gives several prescriptions which have answered the purpose finely in his experience, preferring an herb tea infused for fifteen minutes, two cups taken with fifteen minutes' interval, half an hour before breakfast. One of his formulas for the herbs is equal parts of flax, flax, flax, saubinet, flax, chamomilla, herb, melissa, peppermint, and rhiz, valeriana. About two tablespoonfuls for the two cups of boiling water.

82. **Treatment of Diabetes Insipidus.**—Posner describes the great benefit obtained in a neuroathenic woman presenting symptoms of diabetes insipidus when she was instructed to chew ordinary chewing gum or its equivalent. The thirst and the excretion of urine were notably reduced, while the urine became more concentrated. Prolonged chewing with the increased salivation is evidently an important aid in the treatment of polydipsia and polyuria.

87. **Operative Treatment of Jacksonian Epilepsy.**—Krause reviews his experience on this subject—12 operations—and on the electric diagnosis of cerebral disturbances. His article is profusely illustrated. In one case the evacuation of an encephalitic subcortical cyst cured epilepsy and mental impairment of long standing in a girl of about 15; the cure has been complete for twelve years to date. Faradic testing of the cortex in the operating room is an indispensable aid in locating the lesion. In one instance it showed exactly the spot at which to look for the tumor. Six cases are described in detail. In one of severe, typical epilepsy, the centers for the finger, hand, forearm and lower part of the face were involved. On exposing these centers nothing abnormal was found, but faradization of the arm center caused an incipient epileptic seizure. The part of the brain containing the above-mentioned centers was resected, the exposed part measuring 23 by 15 by 20 mm., and to a depth of at least 5 mm. There have been no seizures since, and the patient is able to attend to a large business, although he occasionally feels a little twitching or cramp in a limb. Among the 12 patients operated on, 2 patients died. In one instance the fatal termination might possibly have been averted by operating at two or more sittings. The other patient suffocated in an epileptic seizure. Recurrence is more probable, Krause thinks, in the cases in which nothing pathologic can be found.

92. **Treatment of Excessive Secretion of Gastric Juice.**—Kittner applies the term gastronyxorrhoea to a condition in which large amounts of gastric juice are secreted by the fasting stomach, even although there may be merely the normal or a lesser proportion during digestion. An acute attack requires prompt lavage of the stomach which will sometimes abort it. Morphin seems to be the only effectual drug. The nervous condition should be treated with general measures, hygienic and tonic. The chronic affection requires frequent rinsing of the stomach. A course of mineral waters may prove effectual in some cases. The results of treatment have not been very encouraging in his experience.

93. **Broncho-Biliary Fistula.** Eicher adds another to the 12 cases he has found in the literature, with an illustration of the post-mortem findings in his case.

100. **Effect of Emotions on Gastric Secretions.**—Among the interesting experiments related by Bickel is one in which a dog with a Pawlow fistula and opening into the esophagus was worried by a cat while he was eating. The curves showing the amount of gastric juice secreted during sham feeding ranged usually between 100 and 190 during the hour following the sham feeding, gradually declining to 80 by the end of the second hour. When a cat was brought in a cage into the room and placed beside the dog while he was being fed, he became very much excited and angry, and only 20 c.c. of gastric juice were secreted during the first five minutes afterward. Examination at five-minute intervals showed that the secretion grew constantly less and less to practically zero by the end of half an hour. In another experiment the cat was not brought in until about half an hour after the sham feeding. The amount of gastric juice secreted had risen from 120 to 275 during this period, but in the next five-minute period, after the dog had been teased by the proximity of the cat, only 20 c.c. of gastric juice was secreted, and during the following hour the amount never increased beyond 60 c.c. The curves show, further, that, although the amount of the gastric juice was thus influenced so decidedly by the emotional disturbance, the digestive power of the juice remained at about the same level, horizontal during the tests, as well as during the undisturbed feeding. Bickel calls attention in particular to the fact that this inhibiting effect of an emotion on the gastric secretion persisted even after the cause for the emotion had been removed. The cat was only left in the room a few minutes, but the gastric secretions were evidently permanently checked for the time being by the dog's temporary excitement.

101. **Chemistry of Leukemic Blood.**—Schumm calls attention to an albumin-splitting ferment resembling trypsin in the blood in cases of leucal myelogenous leukemia.

103. **Cystoscopy and Lithotripsy in Different Positions.**—Ringel gives illustrations of a table which allows a patient to be catheterized while lying face downward. There is a semi-circular recess in the lower end of the table which allows the catheter to be inserted readily in this position. It offers several advantages, as he describes. He calls it the "under the abdomen position," and commends it also for lithotripsy. He also advises changing the position to aid in catheterization.

105. **Results of Koch's Year of Research in Eastern Africa.**—The main results of Koch's scientific trip to Africa were summarized in the news columns on page 1888 of the last volume of THE JOURNAL. In this article there are twenty-four illustrations showing the various forms in which the spirillum of relapsing fever was encountered in ticks, the development of the protoplasmic bigemium (of Texas fever), and of the germ of "east fever" in cattle, and of the trypanosoma and tsetse-fly. He found that the tsetse-fly disease is transmitted by the *Glossina pallidipes* and *fusca*, as well as by the *morsitans*. It has proved impossible hitherto to infect the glossina by allow-

ing it to feed on animals having trypanosomes in the blood from recent infection. The flies did not become infected until the cattle had been infected for some time, and their blood contained only a comparatively small number of the germs. Koch thinks that this shows that not all trypanosomes circulating in the blood are capable of infecting the tsetse fly. They must be in some certain, and to us still mysterious, condition before they can transmit the infection. This condition may occur in wild animals. He has found infected flies at points where they probably could only have become infected from wild antelopes or buffaloes. The trypanosoma passes through a certain phase of its development in the body of the glossina.

107. Morbidly High Arterial Pressure.—Krehl regards the higher arterial pressure in nephritis as a compensating measure to insure the elimination of urine-forming substances. If it is possible to reduce the formation of these urine-forming substances, then the arterial pressure will spontaneously subside. This is the explanation for the benefit from a milk diet in nephritis. When nothing is ingested but milk, the arterial pressure rapidly sinks. In impending uremia, repose, dieting, sweating, and blood-letting will relieve the organism of a certain proportion of the urine-forming substances which it is seeking to eliminate by increased arterial pressure. These measures should be supplemented by others to strengthen the heart if necessary to enable it to aid in this elimination. The high arterial pressure is needed in granular atrophy of the kidney to compensate the defective functioning, and our aim should be to reduce this task to the minimum. It is unwise and dangerous to think that we must always strive to reduce by direct means the high arterial tension in all cases. It is fortunate that Nature resists such measures so obstinately.

108. Surgical Treatment of Brain Affections.—Krause describes in detail the present status of operative treatment of abscesses in the brain, traumatic epilepsy, tumors and injuries, with the indications for special technique.

109. Placenta Praevia.—The points specially emphasized by Fritsch are that the tampon should be applied with the patient lying on her side, with the bladder and the rectum emptied. The genitalia must be disinfected frequently and the vulva washed off repeatedly before, during and after the tamponing with cotton soaked in a reliable disinfectant. By repeatedly washing off in this way the parts are kept comparatively sterile. The best instrument for introducing the tampon is the hand. The hand of a cautious obstetrician is less dangerous than a metal dilator. It is possible sometimes slowly to dilate the os with the fingers and to push it back over the head of the child without lacerating it in the least. He gives a number of other points to be borne in mind and describes the technique he prefers.

110. Bleeding from Female Genitals.—Döderlein expatiates on the necessity for adapting treatment to the cause inducing the hemorrhage. Any bleeding after definite cessation of menstruation should be regarded as pathognomonic of cancer. A myoma does not induce hemorrhage directly, as a rule, but it is the cause for long persistence of menstruation and for severe bleeding at the periods. Bleeding from the genitals between the ages of 15 and 45 is not characteristic of any special affection, but indicates some gynecologic disturbance which should be differentiated.

111. Infantile Digestive Disturbances.—Hochsinger concludes this postgraduate lecture with the remark that to date we have no causal therapy, in a chemico-bacteriologic sense. The Breslau school regards the albumin in the milk as of little moment, while Biedert and his school consider it the main factor in infantile digestive disturbances. The safest way is to withdraw all or nearly all food from the child and then to resume it very slowly and by degrees, watching the effects.

112. Acute Angioneurotic Edema.—In Herter's case the edema developed always after midnight, reached its maximum toward morning and then gradually subsided during the forenoon. The patient was an otherwise healthy woman of 69. The edema was restricted to the lower part of the face and tongue. The attacks have recurred at intervals of a few weeks or months during the last eight years.

114. Congenital Obstruction and Stenosis in the Alimentary Canal of the New Born.—Kreuter shows by his embryologic studies that the lumen of the fetal alimentary canal is liable to close up by cell proliferation from the fourth to the tenth week as a process of development. When stenosis is observed in the new born it is the abnormal persistence of this embryonal process. He has been able to find reports in the literature of 111 cases of atresia of the esophagus, 8 of the stomach, 5 of the duodenum, 103 of the jejunum or ileum, and 33 of the rectum. He completes his extensive article with a number of plates illustrating the embryonal process described.

118. Foreign Bodies in Male Urethra and Bladder. The literature of 750 cases is reviewed by Englisch after report of 10 cases from his own experience. The results were more favorable when the foreign body was in the urethra, as only 7 deaths occurred in 181 of these cases, while the mortality was 30 deaths in 625 bladder cases (mortality, 3.87 per cent. and 5.86 per cent., respectively). Spontaneous expulsion occurred in 4.28 per cent. of the bladder cases and in 3.31 per cent. of the urethra cases. It is easier to crush a foreign body in the bladder than in the urethra (10.58 per cent. and 2.2 per cent., respectively). Foreign-body operations on the urethra have a mortality of 2.17 per cent.; on the bladder, 8.17 per cent. High incision gave the best results and lateral perineal incision the poorest, the mortality being, respectively, 1.66 per cent. and 10 per cent., while that of the median perineal incision was 4.44 per cent. When the foreign body is incrustated, unless it can be broken up and removed in fragments, operative treatment insures the best results, much better than prolonged attempts at instrumental extraction. Scraps of bone have frequently been spontaneously expelled from the bladder, but pieces of a catheter usually cling to the bladder wall and are seldom spontaneously expelled. Experience has abundantly demonstrated that if a foreign body in the urethra or bladder is not removed it is almost sure to entail inflammation, gangrene or a fistula, generally leading to fatal pyemia. Spontaneous expulsion has been known to follow injection of oil into the urethra, also after closing the outlet when urinating, the accumulating urine washing out the foreign body, especially when the passage has been previously stretched to its utmost capacity by introducing a large sound as far as the foreign body. Less than a dozen cases of such spontaneous expulsion are on record. Twenty-seven kinds of foreign bodies were found in the 750 cases reviewed, a piece of a catheter in 220, hat pins in 41, pieces of bone in 59, knitting needles in 32, bullets in 24, wax candles or tapers in 21, pencils in 12, and paraffin, wads of hair or fiber in 5 each. The age of the patients ranged from under 5 to over 80. The monograph fills 89 pages.

119. Length of Survival of Epidermis Cells. Burkhardt announces that epidermis cells retain their vitality unimpaired for several days. His experiments were made on dogs; the

conditions are more favorable in man. The cells require oxygen and asepsis to keep perfectly. They should not be kept in a fluid, as this macerates them; neither should they be allowed to dry out completely. The vessel in which they are kept should not be air-tight. The best results were obtained with scraps kept warm and moist. They retained their normal aspect and elasticity.

141. Length of "Karlsbad Cure" for Gallstones.—Fieber die Dauer des Kurbesuches in Karlsbad beim Gallensteinleiden. E. Hertzka.

126. One-Day Pneumonia.—Bechtold states that out of 1,057 cases of pneumonia at the Würzburg clinic, 10 were what might be called "one-day" pneumonia. The chill, high fever and crisis were observed in all, but the percussion and auscultation findings differed materially. The sputum was rusty in only one case, but traces of bright red blood were visible in another. Four of the patients were far from being robust, and these cases seemed to be due to a mild house contagion, all occurring close together in one ward.

129. Injuries of Spleen.—Graf relates the particulars of 3 cases of injury of the spleen, blunt wounds in 2 and laceration in the other case, which terminated fatally from internal hemorrhage. The spleen was removed in the other patients. One was a man of 66, and the remarkably slow recovery was a noticeable feature. It seemed as if the lack of regeneration of the blood from the absence of the spleen retarded convalescence. An accessory spleen was found in the other patient, a young man of 27, and his prompt recovery may have been facilitated by the presence of this compensating organ. The blood findings were quite normal by the eighth week.

130. Clamp for Penis.—The clamp described in this article is to take the place of the fingers when closing the lumen of the urethra to prevent reflux of medicinal fluids introduced.

136. Double Sepsis.—Stübli cultivated the *Streptococcus longus* from the case of sepsis reported, but found, further, that after six days a new and hitherto undescribed bacillus developed on the media and had evidently been partially responsible for the sepsis. The necessity for waiting several days to determine the true causal agent or agents is emphasized by this case. Even the cultivation of one germ does not exclude the possible presence of others. In the case reported, the Widal test was positive at 1 to 200, but nothing was found to explain this fact, no signs of typhoid being discovered.

138. Cyrtorhyetes Lesion. Jancke found Siegel's cyrtorhyetes, exactly as he has described them, in 10 placenta from women known to be syphilitic. Control examination of placenta from normal women always resulted negatively. Siegel's technique was described in the *Münch. med. Wochschr.*, 1905, Nos. 28, 29 and 32. Jancke obtained the best specimens by staining with azur for twenty-four hours, rinsing for half an hour in distilled water, and then drying in the air. They were then dipped for one or five or eight seconds in alcohol, then in xylol, and mounted in balsam.

139. Prevention of Puerperal Fever. Lingel urges that midwives be forbidden to make vaginal examinations of pregnant or parturient women.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or to the interests of our readers.

Addresses

THE PRESENT STATUS OF THE SURGERY OF THE STOMACH.*

WILLIAM D. HAGGARD, M.D.
NASHVILLE, TENN.

The triumphs which surgery has achieved over certain diseases of the stomach comprise one of the most useful and gratifying experiences which has crowned the efforts of our profession in the last decade. It has demonstrated anew that, as the hand-maiden of medicine, surgery is ever widening the limits of its helpfulness and adding new luster to its already brilliant achievements.

The stomach is probably the most important viscus in the body from a surgical standpoint. It is more prone to pathologic changes that can be relieved by operation than any other portion of the alimentary tract, save its terminus. Interference with its functions are attended with the most distressing and serious results. The relative safety with which it can be exposed and manipulated goes far to render it attractive for needed surgical exploration. Its thick walls and peritoneal investment make it well adapted to suturing, and wounds and incisions can be closed with ease and security. With the perfection which the details and accessories to surgical work have been brought in other departments, the comparatively recent innovations in the surgery of the stomach have been undertaken with a precision which has not obtained in the opening up of other new fields in the surgical domain. The mortality in the hands of the expert has been so minimized that operation can be consistently advocated for the relief of distress and disability as well as for immediate and remote danger.

The modern surgery of the stomach is not more than four or five years old, and in its more perfected aspect is only half that old. Its results, judged by statistics before that time, are not comparable to its present accomplishments and the oft-repeated reference to its "frightful mortality" should give place to the recognition of its present surprisingly low death-rate. The discussion, relative to operation for stomach lesions now, is similar to that in regard to appendicitis twelve or fifteen years ago. Then only the desperate cases were submitted to operation. It is so now with many stomach cases. This, however, must yield to the logic of results and in a short time the profession generally will advise early operation as they now well-nigh universally do in appendicitis. Improved technic, low mortality and satisfactory end results will inevitably do away with the empirical treatment of occult intractable stomach troubles. Operating-room demonstration of pathology *in vivo* is impressing the easy mechanical relief of these lesions. A

closer intimacy with living pathology will instill the lesson which we have learned so well in other portions of the body, where the golden opportunity is no longer permitted to slip away.

The laity, too, will soon become educated on the subject, and will criticize us for allowing a chronic ulcer to go on to perforation or fatal hemorrhage and for permitting cancer to stealthily creep upon its unsuspecting victim without early recognition. They did that with cancer elsewhere, with delayed operations for appendicitis and with the occurrence of puerperal sepsis, and in my opinion the laity had a very strengthening influence in seconding our efforts to prevent these catastrophes.

Penzoldt appeals for a closer union of surgical skill and internal diagnosis, and says it promises more for patients with a stomach trouble than for any other morbid condition. He says:

It is the duty of every practitioner who has not the fortune to possess the necessary experience for performing these operations to call into consultation a surgeon possessing the necessary skill so soon as the question of any operation arises. Above all, it behooves the physician who practices as a specialist in the domain of stomach and intestinal diseases, and to whom a great number of incurable patients are sent, to come to a definite agreement on the grounds for operation with an experienced surgeon; the unavoidable disadvantages arising from the unnatural division of practice into surgery and medicine may by such a personal union be compensated.

Moreover, he warns physicians that although there may be a good deal of difficulty in acquiring the necessary skill in the diagnosis of stomach diseases, this is far easier than that required to perform the necessary operations, and that if physicians do not co-operate with surgeons the latter will find the means of acquiring the diagnostic skill and do without them. He complains, too, of the "hesitation and faint-heartedness" of many practitioners which he thinks constitute an unjustifiable obstacle to the progress of surgical treatment (Saundby).

Granted the diagnosis, the surgical problem has just begun. The literature abounds in most complete and exhaustive memoirs. Surgical inquiry and activity in this field is everywhere rife. Various methods have been employed. The technic is constantly changing. The ingenuity displayed in the planning of operative methods is really wonderful. The discarding of the unessentials is very striking. Simplification of mechanics and technics seems to be the desideratum. Mayo is working on a new plan in gastro-enterostomy which tends to simplification and, it is believed, to better mechanics. It is not untimely, however, in this presence to invoice the present attitude of advanced professional thought and epitomize the recognized methods of to-day. I will endeavor, therefore, to present some facts which I believe faithfully portray the present status of the surgery of the stomach.

*The address in Surgery before the Mississippi Valley Medical Association, Indianapolis.

The typical indication for operative interference is obstruction of the pylorus from an open or cicatrized ulcer causing dilatation of the stomach with stasis of food. The short-circuiting operation of gastro-enteric anastomosis finds its ideal indication here and has given most beneficial results. It is the *fons et origo* of the present group of drainage operations, as well as other gastric procedures, and is altogether the most perfected and satisfactory employed operative device.

The complications of ulcer requiring operation are (1) perforation and (2) hematemesis of chronic ulcer. Hemorrhage from an acute ulcer is rarely fatal and is usually amenable to dietetic treatment.

It is often the first symptom of acute ulcer, but rarely occurs in that relation to chronic ulcer and makes its advent most often between the first and fifth years of the disease. It occurs in 18 per cent. of all cases (Fenwick), causes death in 8 per cent. of those in which it does occur (Rodman), and is the determining cause of death in from 3 to 5 per cent. of all cases (Welch).

Operation is advised in repeated acute hemorrhage or in constantly recurring small hemorrhages.

Other indications are found in the following groups of cases: (3) Obscure and persistent stomach symptoms with a long history of dyspepsia culminating in hemorrhage, after it has been controlled by medical means and the patient put in the proper condition for operation (Cahot). (4) Cases of chronic intractable dyspepsia even without dilatation which fail to yield to proper medical treatment and are not due to general visceral ptosis.

Waterhouse says that unless definite improvement manifests itself after three months of medical treatment of chronic ulcer or all serious symptoms have not disappeared after six months' treatment the case should be considered one for surgical, rather than for continued medical aid.

Other authors specify operation in cases in which "three" systematic ulcer cures have not cured, and a prominent surgeon facetiously remarks in reference to these cases that operation is contraindicated unless the patient has had as many as nine permanent and complete cures. The greatest desideratum in gastric surgery is operation in the early stages of cancer, and hence in enumerating the indications it may be summarized in the phrase (5) "on suspicion of cancer." A synopsis of the other stomach conditions for which operation is recommended is as follows:

- (6) Disabling perigastric adhesions.
- (7) Congenital stenosis of pylorus.
- (8) Fistula between stomach or pylorus and adjoining organs or even with the surface of the body.
- (9) Hour-glass stomach.
- (10) Congenital hour-glass stomach (Brooks).
- (11) Volvulus.
- (12) Tetany due to obstruction and dilation (Cunningham).
- (13) Spasm of pylorus (Reichmann's disease).
- (14) Subphrenic abscess.
- (15) Perforating wounds of stomach.
- (16) Non-perforating trauma (Monprofit).
- (17) Cirrhosis (Sheldon).
- (18) Foreign bodies.

It will be seen that, aside from malignancy, chronic ulcer and its complications furnish most of the indications and the majority of cases. Indeed, it is not impossible that the bulk of cases of inveterate dyspepsia are really due to ulcer. That it is found postmortem so very many more times than it is recognized clinically is

a reproach not so much to our diagnostic measures as to our failure to properly apply them.

The necropsy incidence in Philadelphia was 3.15 per cent.; in London, 4.6 per cent.; in Europe, 8.54 per cent. Mikulicz says: "The dangers to life from gastric ulcer is at least not less, but probably far greater than the danger of a complete modern operation." Riegel estimates the mortality at 8 to 10 per cent., Lebert at 10 per cent., Welch at 15 per cent., von Leube at 25 per cent., Debove and Raymond at 50 per cent.

Aside from its immediate and remote mortality (anemia, tuberculosis, malignant degeneration, etc.), the ease, frequency and permanence of cures are greatly overestimated. In a consideration of the permanent cures it must be borne in mind that amelioration of acute symptoms does not necessarily mean an actual cure, and some of the patients so cured may and do die later of perforation, hemorrhage, canceration and other complications, and 40 and 45 per cent., respectively, in two different series of cancer cases represented a good history of preceding ulcer (Mayo and Graham).

As bearing on permanence of cure, Russell studied 89 cases of gastric ulcer, covering a period of 7½ years; 44.7 per cent. were found to be suffering from stomach symptoms at the last report, 14.9 per cent. were having repeated and definite attacks with intervals of immunity, and 29.8 per cent. suffered almost continuous pain. Another group of 6 per cent. could not as yet be classed with the uncured, 44.7 per cent. Contrast this very lame showing to the graphic description and beautiful results of Moynihan:

Indeed, I do not know any operation in surgery which is more successful or which is attended by better or more striking results than gastro-enterostomy for chronic ulcer of the stomach. A patient, thin, shrunken, cadaverous and gloomy in aspect, who has been chiefly occupied in trying to avoid acute attacks of indigestion or vomiting, whose whole attention is concentrated on his stomach, who considers every article of diet carefully before he takes it and by degrees abandons first this dish and then the other until he is finally reduced to fluids alone, who, indeed, has never conceived that any other question than that of his own health could seriously interest him, a patient, to say the truth, whose whole existence has been ordered and regulated by his stomach, finds, after a gastro-enterostomy has been performed for his chronic ulcer, that he can eat what he likes in any quantity he likes, that he rapidly puts on weight, and that his general sense of well-being is almost beyond belief. From being a misanthrope he becomes an enthusiast and an optimist. I have often wondered with a certain amusement what would have been the result of a timely gastro-enterostomy on Thomas Carlyle. He might have taken to the writing of coanodics and threatened the throne of Congress. And his portrait, twelve months after the operation, viewed side by side with that done by Whistler, would have proved an eloquent advertisement for his surgeon.

The ulcer is recognized at operation by its shot-like feel or when the walls are picked up between the finger and thumb the muscularis does not slip off the mucosa. a milky white spot often denotes its site and the enlarged "sentinel gland" of Lund may be found in the greater or lesser omentum. Very often the thick-based, indurated ulcer is so prominent that "he who runs may read" and is situated at or near the pylorus. The induration or contraction may have caused obstruction and consecutive dilatation.

The first four inches of the duodenum is embryonically, physiologically and surgically a part of the stomach. Duodenal ulcer, therefore, does not differ etiologically from it. It is most frequent in men, and in the fifth decade of life. It occurs often in the professional

classes who live too well and develop hyperchlorhydria. It is characterized by pain an hour before meals or in the early morning hours and relieved by food. Malena is frequent. It is relatively very much more frequent than has been supposed. In a period of $2\frac{1}{2}$ years the Mayos found, out of 231 cases of gastric and duodenal ulcer, the duodenum to be involved 2 times, or 32 per cent. In 42 operations for chronic duodenal ulcer he had only a single death. It is exceedingly prone to perforate and takes place usually in men in the prime of life, with perhaps little or no stomach symptoms. Murphy says perforating duodenal ulcer is practically impossible to diagnose accurately without exploratory laparotomy. As a most remarkable series of cases I will quote Turner, who saved 8 out of 9 cases at St. George's Hospital. They were operated on 4, 5½, 10, 12, 17, 24 and 48 hours, respectively, after onset of symptoms. The only unsuccessful case was operated on the third day, when practically moribund.

D'Arcy Powers gives the following forceful description of a typical example of chronic duodenal ulcer:

He tells you that he is a martyr to indigestion, and that for months past he has suffered atrocious pain in his stomach, which is relieved by vomiting. He has dieted himself in every possible manner, he has made all kinds of local applications to his abdomen, he has visited all sorts of watering places, and he has gone in vain from one physician to another seeking a cure. Examination shows him to be a mere bag of bones, badly constipated, cold extremities, and a listless, dejected aspect. His abdomen is loose, the subcutaneous veins dilated, and a visible peristalsis from left to right in the epigastric region. Percussion tells you that the stomach is greatly dilated, and it is not very unusual to feel a tumor in the neighborhood of the pylorus or gall bladder, and you question the patient a little more closely. He is sure that he has been suffering for years, for so long, in fact, that he hardly recollects the beginning of his trouble. A few well-directed inquiries may elicit that twenty-five or thirty years ago, when he was a young man, he once or twice brought up a large quantity of blood without serious pain or discomfort, or that he had an illness which no one seemed to know much about. He was treated for gallstones, or appendicitis, or simply for "liver." The attack was painful and kept him in bed, but the exact details have passed from his mind, and for some years he was as healthy a man as ever.

This is a case of duodenal obstruction resulting from cicatrization of an old ulcer, the irritation of which has caused inflammatory thickening in the surrounding parts. How many patients have been allowed to die of such a condition in the belief that they had malignant disease of the stomach no one can tell. But for such patients a gastrojejunostomy holds out the prospect of a speedy and perfect cure.

It is in duodenal or pyloric obstruction that gastroenterostomy finds its most exquisite indication and attains its highest efficiency.

The many various methods for performing gastroenterostomy give a feeling of wonder at the ingenuity displayed. It is probable that the ideal method has not been finally arrived at. The relative safety of the operation even by varying technic is illustrated by Robson's results—over 200 cases, with a mortality of 3.6 per cent. The posterior operation has largely supplanted the anterior, because of the avoidance of the loop around the transverse colon, and the mischief which it caused. The anterior operation is reserved for malignancy where the speediest technic is the best, where the stomach can not or should not be delivered freely, and the operation is palliative in its intent. The Murphy button, to which we owe most of the knowledge we have of gastric and intestinal surgery, can be employed here on account of its rapid insertion.

The McGraw ligature finds its best scope in such cases if an immediate opening is not required. Secondary jejunal ulcer is not likely to occur on account of the absence of HCl.

The vicious circle, which was formerly a *bête noir*, was due to angulation or obstruction by spur-formation. The posterior loop, eight or ten inches long, invites this more than any other method. It rarely occurs with the button, because of the rigidity at the anastomosis, which prevents kinking.

The posterior operation without the loop, with a longitudinal incision from one to three inches from the duodeno-jejunal angle, gives almost complete immunity from the vicious circle. This operation was described by Petersen in Czerny's clinic, has been recently popularized by Moynihan's writings and is practiced by the Mayos, who have come back to it after employing various other and more complicated and elaborate methods, including entero-anastomoses, with occlusion or division of the efferent limb. The essentials of the present perfected posterior operation are: (1) The selection of the very bottom of the stomach (Mayo); (2) the obliquity of the opening from above down and from left to right (Moynihan); (3) the utilization of the jejunum as it drops straight down and at a point where it normally lies in contact with the posterior wall of the stomach with only the mesocolon intervening (Petersen); (4) anastomosis effected with clamps and simple suturing with linen thread.

Peptic ulcer is not so likely to occur because the mucous membrane is better able to protect itself nearer the alkaline biliary and pancreatic openings.

This technic has enabled Moynihan to report 173 operations for benign conditions, with only two deaths. Mayo performed 307 operations by various methods, with 19 deaths (6½ per cent.). In the last 140 there were only four deaths (2 6/7 per cent.), and in the last 80 by practically this method there was only one death. Mayo, for the last two months, has been making the anastomotic opening obliquely from above down and from right to left, instead of vice versa, as in "Moynihan's oblique line." Heretofore great consideration has been shown the line of peristalsis of the stomach, but Cannon and Blake have shown that, no matter where the opening is made, the stomach by its rhythmic, milking-like action makes the point of exit the lowest part of a spindle and ejects the food in jet-like movements.

All of our past trouble has been with the jejunal side of the anastomosis and not with the gastric. The right oblique opening is in more harmonious relation to the course of the jejunum at that point than the left oblique and prevents twisting the jejunum out of its right oblique direction into the left oblique.

I have employed this technic in three cases recently, with most ideal results so far.

The more complex methods, like Mumford's and Roux's, while most ingenious, are not believed to be more effectual than the simpler methods above outlined. The Roux method is excellent as a secondary operation when vicious circle has occurred.

The gastro-duodenostomy of Finney seems ideal and makes the pylorus capacious and is at the natural outlet. It is contraindicated where there is a large amount of scar tissue and immobility from extensive adhesions. The mortality reported by Mayo was 6.9 per cent. in 53 cases.

Excision of the favorably situated and apparently

solitary ulcer may be advantageously combined with it. There have recently been proposed a number of modifications of gastro-enterostomy.

1. Maury substitutes for the elastic ligature of McGraw a triangular stitch of twine which is effectual.

2. Gilbert uses a Pean forceps containing a sheathed knife to cut through the juxtaposed stomach and jejunum which are united by a continuous serous suture.

3. Werelius experimentally employed silver wire or thread introduced like McGraw's ligature and made to saw through the two adjacent walls when the suture is half completed.

4. Sato proposes to effect the opening by the application of AgNO_3 after the seromuscular coats have been incised and then they are sutured as usual. The lumen is not opened primarily.

A most logical operation for gastric ulcer is that proposed by Rodman, of excising the ulcer-bearing area by a pylorotomy. This stops the possibility of hemorrhage, removes the lesion and cicatrices. This removes also all of the ulcers, as they are usually multiple and situated in the antrum pylori, which is also the cancer site. It removes any co-existing duodenal ulcer in the first two and one-half inches.

There are two classes of cases in stomach surgery that do not give good results: (a) Ulcer with an open pylorus, sometimes allowing the anastomosis to close, and invite the repetition of the ulcer; (b) the neurasthenic, that most-to-be-pitied of all non-fatal diseases. In surgery generally these cases are bug-bears and should be studiously avoided, except in cases of very extreme disability and unmistakable evidence of gross and serious pathology.

The most crying need in all medicine is some means for the early recognition of cancer of the stomach.

The early diagnosis of the other great scourge of mankind—tuberculosis—is satisfactory, but unfortunately there is as yet no radical cure for it.

If it were possible to diagnose gastric cancer in its very incipency, a very large number could be saved by operation. The anatomic and lymphatic conditions are favorable for an ideally early operation.

Until the magic and immunizing therapy which will convert malignancy into benignancy is discovered, extirpation is our only resource.

One-third of all carcinomata are in the stomach. The average duration of life is nine months. Diagnosis by medical means is usually too late unless it is made by a strong surmise and confirmed by exploratory incision. Laboratory methods are unavailing in the operable period, as no change has taken place in the secretions. Any obscure digestive case, where pernicious anemia is excluded, and especially if HCl is absent, demands exploration. Riegel asserts that better results in gastric cancer will only come when the internist acquires the diagnostic acumen to strongly suspect malignancy and possesses, in addition, the courage necessary to enable him to act on that suspicion before it becomes a certainty. Persistent digestive cases should be watched carefully for a few days or weeks only. If there is progressive but slow development of disordered function with pain or vomiting, impaired secretion, emaciation and especially tumor, the wisdom of prompt exploration should be frankly put before the patient.

Czerny's dictum that the presence of a tumor is too late for operation has been disproved by Korte's experience. Thirty-four out of 38 resections had a tumor. The absence of early obstruction is one reason why

symptoms are so illusive, and hence the advent of a tumor is a fortuitous circumstance that by its obstructive symptoms urgently compels diagnosis that should lead to early interference. Nordmann, out of 126 cases, found only one out of four where removal of the tumor was practicable. This is a sad diagnostic commentary.

If exploration proves the condition inoperable, the wound should be closed with buried non-absorbable sutures, and the patient gotten up and out of the hospital at the end of a week. If obstruction is serious, a quick gastro-enterostomy is relatively safe. Robson had only one death in 24 palliative operations. Relief from pain and vomiting is most grateful and life is often prolonged for many months and in a good many instances to a year or longer. The danger of an exploration is not *per se*, but in ill-advised and overzealous efforts to attempt interference in conditions that should be left severely alone.

A writer in the last six months quotes a mortality of 70 per cent. in operations for malignant disease with adhesions and 27 per cent. without adhesions. These figures are tremendously too high and do not represent the possibilities of the modern operation nor the results already obtained which have reduced the death rate from operation to 4 or 5 per cent.

The Mayos in 114 malignant cases had twenty-one deaths, or 18 per cent. There were 63 pylorotomies and partial gastrectomies, with eight deaths, or 13 per cent. The worst cases had only a gastro-enterostomy and the severity caused the high mortality. In the last 41 cases for malignant disease operated in the last twenty-two months the mortality was only 8 per cent.; 25 consecutive, with only one death, 4 per cent. As to ultimate results in 70 cases of resection, four lived more than five years, 9 were still living from one to five years, a number are well after two years, and a majority lived over one year. Of the 16 operated over three years ago, four are living, or 25 per cent.; one is alive and well after four years and ten months. Of Korte's 22 patients who survived the operation, 13 lived from one to five years, 9 were still living from one to five years. Kocher had 45 cases of partial resection since 1898, with mortality 17 per cent., as against 44 per cent. in 52 resections previous to 1898. The strictly operative mortality was really only 5 per cent.; 20 of the 97 were living, 10 having survived more than two years. Petersen, in 18 cases successfully undergoing resection more than three years ago, had 7 alive and 4 had lived twelve, eleven, five and four years, respectively.

The late lamented Mikulicz, who did more than any other contemporaneous European surgeon for the advancement of gastric surgery, obtained a permanent cure or immunity for over three years in 16 per cent., and sadly enough he at last fell a victim to the dread malady for whose alleviation he had done so much. He cheerfully assented to exploration at the hands of Eiselsberg, and when it was found inoperable, he recovered and continued undauntedly at his work until the end. Than this there is no greater heroism.

A description of partial gastrectomy is as follows (Mayo):

Step 1. Open the abdomen.

Step 2. Double ligate and divide the gastric artery. Ligate and divide the necessary amount of gastro-hepatic omentum close to the liver, leaving most of its structure attached to the stomach. Double ligate and divide the superior pyloric artery and free the upper inch or more of the duodenum.

Step 3. With the fingers as a guide underneath the pylorus, in the lesser cavity of the peritoneum, ligate the right gastro-

epiploic or gastro-duodenal artery, and progressively tie and cut away the gastro-colic omentum distal to the glands and vessels up to the appropriate point on the greater curvature and here ligate the left gastro-epiploic vessels.

Step 4. Double clamp the duodenum, divide between with the cautery leaving one-fourth inch projection. With a running suture of catgut through the seared stump, the end of the duodenum is closed as the clamp is removed. A purse string suture about the duodenum enables the stump to be inverted. The proximal end of the stomach is double-clamped, along the Mikulicz-Hartmann line, divided with cautery, leave one-quarter inch in projection.

Suture through the seared stump with a catgut buttonhole suture.

This is again turned in, after removal of the clamp by a continuous silk or Cushing suture.

Step 5. Independent gastro-jejunostomy.

Step 6. Closure of the wound.

Peterson says:

Resection is practiced more than it was because: (1) Resection is not more hazardous than gastro-enterostomy. Twice as many patients die from pneumonia after the latter than after the former operation. The removal of the decomposing cancerous tissue appears to be of great value. (2) The prospect of radical cure is much greater than was thought. The stomach and duodenum must be excised as widely as possible. (3) Even when recurrence takes place, resection prolongs life on an average about nine months, as opposed to the four to five months of its rival.

SCIENCE AND ART IN MEDICINE.

THEIR INFLUENCE ON THE DEVELOPMENT OF MEDICAL THINKING.*

JOHN C. HEMMETER, PH.D., M.D.

Professor of Physiology and Clinical Professor of Medicine, University of Maryland.

BALTIMORE.

IS MEDICINE A SCIENCE OR AN ART?

Medical men the world over frequently have to hear the criticism, I might call it the reproach, that medicine is not a pure science, that its methods and its discipline are not sufficiently accurate to merit this term. On the other hand, critics are not wanting among the non-medical public, who argue that medicine is not a perfect art.

Now, what is an art, and what is a science? In a recent address President Ira Remsen¹ attempts to define these terms, and on the authorities there quoted by this versatile educator we might profitably start out by borrowing the interpretations of the terms science and art. One writer says: "The distinction between science and art is that science is a body of principles and deductions to explain the nature of some matter, and art is a body of precepts with practical skill for the completion of some work. Science teaches us to know, and art to do. In art, truth is a means to an end, in science it is the only end. Hence, the practical arts are not to be classed among the sciences." Another writer says: "Science and art may be said to be investigations of truth, but one, science, inquires for the sake of knowledge, the other, art, for the sake of production. Hence, science is more concerned with the higher truths, and art with the lower. Science is never engaged, as art is, in productive application."

These definitions are apparently not equally clear with regard to science and art. With regard to science, they are clearer than with regard to art. Science has

for its object the accumulation and systematization of knowledge, the discovery of truth. This part is clear, and also that art is a body of precepts with practical skill for the completion of some work. But it is not clear how truth is only a means to an end in art, and in science it is the only end. Surely, if a truth could be expressed as a precept in as concrete a form in any art as it could be in a pure science, it would be, or at any rate should be, the only end, the only object of the art as well as of the science.

Then the question might arise, What are higher and what are lower truths? In the decision much depends on the individual standpoint of the judge. What is a higher truth for a scientist may be a lower truth for an artist, and *vice versa*. If it is said that in art truth is a means to an end, we have a right to inquire what is meant by the truths of an art? For instance, are counterpoint, thorough base, and harmony the truths of music?

I know of but two individuals in the history of the modern scientific world who, by training and experience, could be considered competent to answer this question, both having been artists and scientists at the same time, of acknowledged ability. One was Hermann von Helmholtz, physicist, physiologist and musician. The other was Theodor von Billroth, anatomist, pathologist, surgeon and musician. Both of these men have given us the benefit of their thinking on the borderland between science and art. Helmholtz, in his "Sensations of Tone," and Billroth, in his "Psychologische Aphorismen über die Musik" (Wer ist Musikalisch). To the student of either of these works seeking information on the questions above propounded, it must soon become evident that an exact and definite distinction between art and science is not always possible; particularly it is not possible in any concrete case. We are, therefore, enabled to meet the critics arguing that medicine is not an exact science nor a perfect art, with the statement that a distinction between these two is by no means possible and that there is much debatable territory between human knowledge and human ability. Medicine did not originate as a science, but by dire force of necessity. For centuries on centuries its treasures were gathered from experience only, and were developed into an art by the genius of its representatives. Professor Remsen¹ was, perhaps, too accurate in attempting to draw a clear and fast line between art and science. Every science is desirous to become an art, and every art tends to become a science. So also medicine. I mean by this that art requires a scientific foundation and that science requires ability to do. In other words, science requires productive application, the power of achievement.

My convictions induce me to differ from my erudite teacher, Professor Remsen. At least, to differ with him in applying the same ideas to medical science as he is disposed to set up for the science of chemistry. In rating the history of the discovery of oxygen and chlorine by Scheele (1774), he lays great stress on what seems to him a fact, that Scheele did not work toward these discoveries with any practical object in view, and, though this work, while it was being done, seemed to be of no utilitarian promise, its value in the light of present-day industry can not be overestimated. It would be very difficult to prove that Scheele worked absolutely oblivious of any practical results that his work might have. It is true that scientific men frequently work from pure love of science, prompted by high ideals and disinterested enthusiasm, but there is often an under-

* Address on occasion of conferring of the degree of doctor of laws (*honoris causa*), St. Johns College, Maryland.

1. "The Age of Science," Science, July 15, 1904.

current of thought which is sometimes discovered in the private correspondence of chemists, that the work they are doing may yet be of utility to their fellow-men, and perhaps profitable to themselves. In medicine, too, we have the history of a large number of unselfish workers. But if they should work purely in following ideals, without any hope of gaining any utilitarian results, they are not medical men in the true sense of the word. Medical science shall and must be useful. A quotation from Cicero is well applicable here: "*Nisi utile est, quod faciamus, stultum est gloria.*" An oft-quoted saying of Bismarck is: "*Die Politik kann nicht im Laboratorium gemacht werden, denn sie hat überall mit dem Menschen zu thun.*" (Politics can not be made in the laboratory; they have everywhere and at all times to deal with the human being.) In an analogous manner one may say of medicine: "Medical science can not be made exclusively in the laboratory; it has always and everywhere to deal with human beings." I said medical science, but I would, perhaps, have been more exact to have said medical art. For science analyzes, it dismembers and disintegrates in order to penetrate into the depths of things, and to study the final microscopic living element, the cell, in its life properties and processes. This is true, for instance, of physiology and anatomy. But art in medicine keeps the whole together, it observes the individual, the human being, in its entirety. Science seeks general laws; art in medicine seeks the personality. The object of all medical science is to help and to heal, and the object of all medical, artistic and scientific thinking is the therapeutic thinking. Scientific facts in medicine may have an absolute value, although they may not be directly useful, but, aside from such an absolute value, the whole art and science for the physician must be concentrated on the desire to aid his patient in regaining health by means of his science and art. Prof. I. Peterson, of Copenhagen, was one of the first to assert: "The attempt to erect the medical clinic exclusively on the achievements of natural science has proven itself to be impossible of execution."

HISTORY OF MEDICINE.

The evolution of medical thinking can best be studied in the history of medicine. From the earliest rudiments among the Egyptians, Romans and Greeks, the first beginning of clinical discipline dates from the Arabic apostles of medicine and the religious medical thinking, which was the custom of the healing monks of the medieval ages, who were the founders of the schools of Salerno and Monte Cassino. A new period begins with Paracelsus, a man who was an excellent chemist for his time, a contemporary of Luther, and based his therapy on a chemical substratum. Paracelsus created the conception of the "*Archeus*," the central ruler of the human organism, which holds all the bodily functions together and regulates them. This idea occurred later in the writings of Georg Stahl, under the name of "*anima*," and even in our time is frequently met with in a disguised form, sometimes under the designation "*vital force*." Scientific thinking, that is, thinking based on observations of objective facts, began rather late in the history of medicine. Not until the foundation of universities did it meet with appreciation and respect. This was brought about mainly by the great anatomists of Italy, particularly by Andreas Vesalius, a German by birth (Andreas Wesel), but professor in Padua, 1537 to 1544. Then followed Malpighi, Botalli, Harvey, the celebrated discoverer of the circulation of the blood, and eventually Morgagni (1682-1771), the founder of pathologic anatomy.

This brings us to a period in the history of German medicine in which this science began its emancipation from philosophic and purely deductive thinking, to the scientific and inductive method of investigation, including severe criticism and testing of facts by exact proofs and experimental research. At the time the battle began in Germany between philosophic and scientific thinking in medicine, the methods of the natural science had already gained victories in England and France, and a new era of logical scientific thinking had begun under Rokitsansky and Skoda in Vienna, but the course of the struggle was most interesting in Germany, particularly in Berlin. It was begun by an intellectual giant of such rare genius and unfailing logic that he might be called the father of exact physiology and medicine in Germany. I speak of Johannes Müller. He was the first to compel the abandonment of the philosophic thinking in medicine, insisting on the methods of the natural sciences, on investigations based on exact facts, on tests by experiment, and on the importance of microscopic investigations. The work of this great master was continued and perfected by two great pupils, Hermann von Helmholtz and Rudolph Virchow. Helmholtz particularly condemned the effects of the volitional thinking of the medical philosophers of his day, accusing them of contempt for exact investigation of the facts. "Natural philosophy in medicine," he says, "aims to explain the phenomena of normal and abnormal life, from the idea of absolutism. It is working toward a false idea of science, in a narrow, incorrect and one-sided appreciation of the deductive methods. It is true it was not only medicine among the sciences which was ensnared in these errors, but in no other science were the evil consequences so evident and did they obstruct progress so effectively as in medicine. The history of medicine, therefore, can claim a very special interest in the history of the development of human thought, for no other history is better adapted to demonstrate that a correct criticism of the sources of our knowledge is practically one of the most important duties of true philosophy." The demands of Helmholtz for exact scientific methods in medicine, when brought into practical execution, succeeded in raising our science to the standard of an exact discipline and brought it into possession of a wealth of solidly grounded facts.

The other great pupil of Johannes Müller, Rudolph Virchow, became the reformer of medicine in another direction. While professor in Würzburg, in 1849-1856, he laid the foundation of his cellular pathology, and later on, in 1856, when he was recalled to Berlin, he continued the work of his great teacher in perfecting the science of pathology and pathologic physiology, based on individual investigations, on experiment and on pathologic anatomy. The conception of a disease became an anatomic conception, through Virchow, but his pathologic anatomy aimed also to fathom the processes of the living body, and to become a beacon light for clinical study, and in that sense was a truly biologic science. For nearly half a century Virchow continued to be the undisputed chief and the greatest authority on the totality of medicine in the civilized world; and it is no exaggeration to say that no other scholar in the history of medicine has exerted a like influence on the thinking of the medical world. As von Leyden says: "He impressed the stamp of his intellect on his time."

This sketch will serve to represent the history of medical thought from the incipency of medicine as an art to the present day. We are now living in the era of the naturalistic, methodic and anatomic thinking in medi-

cine. What influence has this had on the artistic side of our profession, the clinic?

MODERN CLINICAL METHODS.

It must be emphasized right here that at the time when Helmholtz and Virchow began to be active in Germany, the methods of the natural sciences had already taken root in Paris, Vienna and in England. During the time that pathologic anatomy found its propounders in Cruveilhier and Rokitsansky in Paris and Vienna, respectively, and at the time in which the clinic of Paris was under the inspiration of Laënnec and the clinic of Vienna under Auenbrugger and Skoda, the German clinic was still dominated by the philosophic medical thinking. von Leyden states that the language of the clinicians was Latin and that they followed the volitional deductive methods of Leibnitz, Kant and Hegel. The first clinicians were Reil, Berend and Bartels. Reil was a natural philosopher, and Bartels had been a teacher of anatomy in Hildesheim, while the best that could be said of Berend was that he was a "thorough connoisseur of the writings of Hippocrates." Hufeland, a clinician of genius and influence, who followed these men, showed "*Was Geistes Kind*" he was by corresponding with the philosopher Kant on his work concerning "Makrobiotik," and expressed himself disparagingly concerning the new diagnostic methods of auscultation and percussion.

But, in 1844, a contemporary of Johannes Müller was called to Berlin, and to this clinician, Lucas Schönlein, is due the credit of having replaced the Latin by the German language in clinical teaching. He brought about the appointment of the very able younger clinicians, H. Simon, Remak and L. Traube. With these men began the methods of exact physical examination of patients. Traube particularly was a master of diagnostic methods.

But when we look to the development of internal therapeutics at this stage of advanced clinical methods in Germany, it is discovered that the attempt to base therapeutics on pathology and diagnosis had failed. Therapeutic nihilism prevailed at Vienna, and the best that could be said of Berlin was that it worshipped the expectant plans of treatment. It took many years to impress on the clinician what now seems to be acknowledged a self-evident fact, that the only object of medicine is to help and to heal, and after the highly interesting evolution of the purely scientific part of medicine, briefly outlined in the preceding sketch, reformers were needed to emphasize again and again that, in addition to a science, medicine was also an art. Peter Krukenberg, a distinguished clinician of Halle, stated this in the following words: "Medical treatment, that is, therapeutics, is and will always remain an art." This conception of the clinical duties and responsibilities of medicine has been designated by Prof. I. Peterson² as "modern Hippocratism." The ultimate object of all medical studying is to help and to heal. The peculiar problem of the physician is not so much the disease, but the diseased patient; and the significance and importance of medicine is to be sought in this object, to protect the highest possessions of human beings, namely, life and health.

RECENT ADVANCES IN MEDICAL ART.

A brief résumé of the advances in the art of applied methods of healing will give some idea of the progress that has been made in our art during the last two dec-

ades. I will begin with three methods of discipline not as a rule classed among the applied therapeutics in the ordinary sense of the term. I mean, first, the physical methods of treatment; secondly, the treatment by diet, and, thirdly, the treatment by the art of nursing and the direct attention to the comfort of the sick.

Concerning the physical methods of treatment, I may say that, while they are by no means new, they have received such admirable and utilitarian additions and developments that modern physical methods of treatment almost constitute a new branch of applied therapeutics. The treatment by baths and water in general, balneology and hydrotherapy, the treatment by exercise and special apparatus for the correction and passive and active motion of diseased muscles, joints and bones, by gymnastics and massage. The wealth of methods by which electricity can be applied, and photo- as well as heliotherapy, the therapeutic applications of different kinds of light, has been endowed with such an abundance of new apparatus and methods that almost each one of them requires a specialist for their perfect application.

The treatment by diet has been placed on the safe and sound foundation of the physiology of nutrition. It has been aptly designated by von Leyden "*Ernährungs-Therapie*." Not only the selection of the quality and quantity of the food, but the manner of its preparation, the cooking, has received attention of medical men, particularly those whose attention is concentrated on diseases of metabolism and of the digestive organs. There are probably few healing methods by which more permanent good can be accomplished in the diseases just mentioned than by a scientific method of dietetic principles. It is much to be regretted that the art of cooking has not yet been universally admitted as an integral part of the curriculum in schools for girls and young ladies. It is unfortunate that in our well-to-do and even in the middle classes cooking is considered a humiliating occupation, a thing in which the modern housewife takes but a very superficial interest, leaving it, in the great majority of cases, to the cook whose experience and ability is a very variable quantity. The health of our people depends largely on the products of the kitchen, and the work of the kitchen is just as ennobling and honorable as any other work in any other walk of life. Cooking should be taught in every nurses' training school; and this brings me to speak of the art of nursing, the direct and immediate service toward the comfort of the sick patient.

Nursing constitutes the ethical factor in the vocation of the physician. It is that part of the applied art of medicine which gives it the character of devotion to suffering humanity, and which invests the physician with the reputation of sympathy and love for his fellow-men and women. Nursing is that branch of applied therapeutics in which our sisters, wives and mothers can join hands with the physician. It is individual and personal, it is the tie which binds the personality and individuality of the physician with that of the patient. Attention to the comfort of the patient and efforts at the widest application of the art of nursing afford also a common ground for two other much to be desired objects of our art: first, to secure for it the greatest possible support from philanthropic individuals and from the state and nation, and, secondly, to unite the more and more digressive specialties in medicine on the common ground of relief to human suffering. Here we have a tendency in which our claims for philanthropic and state support find a real and enduring sentiment and justification. For we can not claim this support for

2. Verhandl. d. Congress f. I. Medicin, 1899.

medicine as a science alone, but we can claim it for medicine as an art. For it is not exclusively the sciences which secure the blessings to the vocation of the physician, but it is the devotion to the relief of suffering, the readiness to help, the sympathy and the kindness of heart.

Right here a word of caution will not be amiss in reference to the ultrabacteriologic doctrines of the causation of disease and their influence on the treatment of the sick. This caution has already been expressed by Prof. O. Rosenbach, of Berlin, viz., we must not let any possible fear of contagion convert our sympathy and love for the patient into fear of the patient. It can not be denied that from time to time a physician or a nurse may contract a disease from the patient. There is no doubt in my mind, however, that for every one of such cases of direct infection there are ten others in which nurses and physicians have actually been protected from the disease by virtue of their very intercourse with the patient. According to the ingenious theory of Ehrlich, very slight infection, sometimes scarcely noticeable by symptoms, may actually immunize an individual against a severe attack of that disease. It has been known to me, for instance, that a family in which there was a typical case of typhoid fever, the blood of the remaining members of the family gave the Widal reaction, yet to all appearances they were in a perfectly healthy condition. The antibodies were being produced in their circulation and tissue cells, preserving them from a severe attack of typhoid fever, not only for the time being, but doubtless for a long time to come, and all this without even getting sick. Therefore, such experiences have led me to agree with Rosenbach in the opinion that intercourse with patients suffering with infectious diseases, especially with light attacks, may be able to protect and immunize the nurse and physician against infection. This does not by any means signify that the ordinary precautions against infection can be thrown to the winds. It is mentioned merely to strengthen the nurse in her devotion to duty and to avoid thwarting of her efforts by fear of contagion.

RECENT PHARMACOLOGY.

After the physical methods of treatment which I have mentioned, those offered by pharmacology rank next in importance. The products of the pharmacist and physiologic chemist have much enriched the armamentarium of the physician. Many new antipyretics have been brought out, medicines have been manufactured in a purer form, and older medicaments of approved value have been changed to a more pleasant form. New and useful medicaments for the production of sleep and the lessening of pain have been brought out. I greet it as a specially valuable advance that several remedies for the relief of pain, which hitherto could only be taken internally, and though very useful for the disease under treatment, yet frequently disarranged the digestive apparatus, can now be effectively administered externally through the skin. It has thus been found that very effective preparations of salicylic acid can be brought into a form which, when brought on the skin, will be so rapidly absorbed that the reaction for salicylic acid can be discovered in the urine within half an hour of the external application. The art of general and local anesthesia has experienced wonderful improvements in apparatus, technique and combination of agents.

Bacteriology has not only brought fertile ideas and facts into the science of pathology, but has opened an inexhaustible field for therapeutics. The discovery of the cure for hydrophobia and anthrax by Louis Pasteur

and the discovery of tuberculin by Koch was soon followed by the antitoxic serum for diphtheria and tetanus by von Behring. In connection with these glorious achievements, serum-therapy began to develop as one of the methods of applied therapeutics. It is true that of the many serums thus far prepared only that for diphtheria and that for tetanus have proved generally useful. The fact that the cholera, plague, typhoid, scarlatina, antistreptococcus and rheumatic serums have so far not proved as effective as those previously mentioned need not discourage further efforts to perfect them.

The explanation of the difficulties of preparing effective serums is given by Paul Ehrlich in his ingenious theory on immunity which has brought the complicated phenomena of immunity nearer to our understanding. The study of the effect of bacteria on the human organism has led to the discovery of the protective substances of the blood, of the toxins and antitoxins, of agglutinins and precipitins, of the cytolytins. It is impossible here to enter on the consideration of that most wonderful and stimulating of modern medical hypotheses on immunity which has been developed by the genius of Ehrlich.³

I desire to call attention to a probable outcome of these studies on immunity, to which I have elsewhere referred⁴ concerning the rôle of intracellular catalytic processes in the pathogenesis of malignant neoplasms. If it be possible so to adapt the blood of an animal to a particular form of cell that its serum shall become specifically destructive of these cells, we have here a possibility for the preparation of serums which will be effective in restricting the growth and perhaps of locally destroying malignant and other tumors. My own studies on the transplantation of malignant tumors lead me to believe that, with a fuller knowledge of cytology, the outlook for such serums will be more promising.

Closely associated to serum therapy is the treatment of disease by extract of animal organs, which is gaining more and more in definiteness and exactness of application. Perhaps the most interesting of these substances is the active principle of the adrenal bodies, epinephrin, first isolated by John Abel of Baltimore. Thyroidin and spermin belong to this class of remedies.

The astounding chemical versatility of the cells of the body, as evidenced in the production of such substances, and the immune bodies to which I have referred before, has forced on us a conception of the cell household as a complicated chemical laboratory. Prof. Franz Hofmeister, of Strassburg, in his essay, "Die Chemische Organization der Zelle," conceives the cell as executing its work by manifold enzymes, each working alone in a special little cell compartment. Thus we have a biochemical conception of the cell processes. This is analogous to the conception of Ehrlich, on which he has built his side-chain theory of immunity. Benedict, on the other hand, Jacques Loeb, and perhaps Wilhelm Ostwald of Leipzig, have developed the biomechanical conception of the cell's work. Virchow's conception was, in principle, a purely anatomic one. Thus we have many varied conceptions of the manner and means by which the cell performs its regular and irregular processes. Though apparently widely digressing, it is encouraging to observe how many of the more important of the results of

3. Aschoff, Ehrlich's Selenkettentheorie, etc., *Zeitschr. f. Allgemeine Physiologie*, vol. 1, No. 3, 1902; also Wm. H. Welch, the Huxley Lectures on Immunity, *Science*, Nov. 21 and 28, 1902; and A Résumé of Recent Researches Relating to Immunity, by T. Mitchell Prudden, *N. Y. Med. Record*, Feb. 14, 1903.

4. *Amer. Jour. of Med. Sci.*, April, 1903.

the biochemical, biomechanic, and the purely anatomic methods of thinking, concerning the cell, are beginning to overlap and even to agree with each other.

SUBJECTIVE AND OBJECTIVE METHODS IN RESEARCH.

It might be argued that methods of thinking can not develop a science in themselves. This is true, for thinking should always be linked with observation and experiment. But, on the other hand, neither observation nor experiment alone can make a science. The formation of conceptions, however, from hardened facts of observation, and logical deductions of experiments, can form and develop a science. Unfortunately for our present methods of advancing medical knowledge, experiment alone has usurped the entire machinery of medical progress, and observation, as well as medical thinking, have been pushed to the background. It can not be sufficiently emphasized at the present time to use the words of Socrates, that "the conception is the fundamental condition of apperception and understanding," and Plato says of the sophists, "In the absence of a correct conception, they hold a learned discourse on the ass, when they mean the horse."

Very regrettable delays and even reverses in the progress of medicine have been experienced by the fact that one or other observer or investigator attempted to build his road into the unknown territory exclusively on one of the methods above outlined, namely, medical thinking, or observation, or experiment. One has criticized the value of thinking, the purely subjective method, another finds fault with the method of observation, a third applies his restrictions to the method of experiment, the purely objective method. This has resulted in an accumulation of a vast amount of scientific building blocks, but there is no coherent complete architecture in the modern science of medicine, and this is at least in part due to the perfectly unnatural separation of the three methods of attempting medical progress. It is very rare to find in modern medical literature even an attempt at a complete scientific plan, and this is largely explained by the fear of most investigators to use the method of medical thinking, or the subjective method, in association with the objective method. Martius (Pathogenetische Grundgedanken) says: "It is a curious thing that the more scientific, the more exact the method of an investigation in medicine, the more inimical to thinking are its advocates." This is, indeed, curious. Why should exactness of a method be associated with hostility to our subjective powers of research, the power of thinking, as a help for the solution of medical problems. Darwin, Haeckel, Julius Robert Mayer, and Helmholtz were not only great investigators, but even greater thinkers. The century that produced steam railroads and the electric light gave us the law of conservation of energy by Mayer, and this law, probably the greatest discovery of the nineteenth century, is proclaimed by those most competent to judge to be the fruit of a purely thinking act, and that the experiment attached thereto was a sequence to the thought. Investigators who pursue objective methods of research, based on experiment alone, pride themselves on their exactness in methods. Exactness and accuracy constitute, in the opinion of the experimentalist, the only and the most logical measures of correctness. But what is this exactness, the painful application of units of measurement, of units of weight, of instruments of precision, of accurately controlled conditions of arrangement in the experiment? What is all this exactness but the translation of a frequently very complicated act of thinking

into manipulations of science? The thought preceded the experiment. The subjective preceded the objective method.

J. P. Pawlow,⁶ most scholarly of Russian physiologists, attacks the adherents of vitalism and animism in physiology in a recent contribution. These terms, vitalism and animism, refer to the tendency to return to the older conceptions in physiology, which attributed the phenomena and processes of life to a "vital force," the "archeus" of Paracelsus and the "anima" of George Stahl, a something which was not explainable by the laws of chemistry or physics. The application of chemistry and physics to physiology has enabled us to understand a great many of the processes of life, and to explain them on a purely chemical or physical basis. But some of the clearest thinkers in physiology admit that many of the processes of life can not be explained on such a basis, and they begin to favor views attributing such life phenomena to a special energy in the living substance (neovitalism). They who favor the vitalistic and animistic aspects of physiology are apt to confuse the standpoint of the investigator of natural science with that of the philosopher. The objective investigator has hitherto accomplished his most far-reaching results by the study and comparison of objective facts, during which he ignored questions concerning the inner subjective nature and the fundamental principle underlying the thing investigated. The philosopher, however, embodies the tendency toward synthesis of thought, and in attempting this he begins by a fusion of objective and subjective phenomena. For the investigator everything depends on the objectivity of the method. This gives the possibility of finding solid and unbreakable facts and principles. This is the view of Pawlow. In my opinion, subjective and objective methods of investigation are inseparable. Even where the investigator believes himself to be purely objective in his methods, he is unconsciously and unavoidably subjective, because the objective accuracy and precision of his methods represent but a translation, an outward projection, of his own subjective train of thoughts, and when his objective facts are established they must again be linked and amalgamated into his own thinking, or that of others, in order to be of value for the progress of knowledge.

DIFFERENCE BETWEEN TRUTH AND FACTS.

We are living in a period in the history of medicine in which the experimental tendency has gained supremacy over speculative philosophy in medicine. But we are in the possession of such an enormous amount of new material and facts, which by additional experiments is daily increasing, that the new facts frequently must be allowed to remain unused, and are, for the time being, of no assistance in the advancement of our science. In this connection, I must again repeat what I have emphasized in the preface of the second volume of my work on "Diseases of the Intestines," namely, the difference between truth and mere facts. These two are often, unfortunately, considered synonymous. Facts are little truths that our senses are capable for the present of comprehending; but back of, and beyond these facts, later experience often reveals the higher and greater truth. An experimental fact which to-day seems absolutely disconnected and, therefore, without meaning may to-morrow, when viewed in another light, suddenly assume a far-reaching significance and importance. No new fact of experience or experiment, be it

5. "Psychische Erregung der Speicheldrüsen" (Ergebnisse d. Physiologie), 3d year, vol. 1, p. 177.

at present apparently ever so remote from practical bearing, need be considered worthless, provided it is correct. It may be allowed to rest as raw material for a time, but it is probable that in another association it may acquire an importance which we did not anticipate.

But this I must emphasize, that an isolated, disconnected fact of experience or experiment has, for the time being, no significance for the progress of medicine. This significance comes only, then, when we can arrange and fix this fact into the already existing and firmly established architecture of our knowledge. There exists a danger in overrating the value of single facts of experience and experiment. Individual facts discovered this way are accumulating to such an extent that we are completely submerged under an ocean of experimental results, and the intellectual interpretation which fits them into the synthetic structure of our science is missing. Physicians who are not participants in experimental undertakings feel very painfully this absence of the connecting link between an enormous number of new acquisitions which, though experimental, are in a sense empiric. This is also true of the experimental acquisitions in bacteriologic as well as biochemic domains. In the eighteenth and during the first part of the nineteenth century medicine was comparable to a sterile unproductive heath, in which some evil spirits drove about the speculating medical philosophers in a circle. Now we have gotten into an overfruitful swamp or jungle in which the facts grow so luxuriantly that they threaten to smother our thinking powers. The tendency of all laboratories is to bring out new facts. Let us have all of them if it must be, but what we need as much, if not more than new facts, are master minds who will instruct us in the interpretation of these and old facts, and give them a meaning and value by fitting them into the synthetic structure of physiology and medicine. Martius compares modern medicine to a sense-confusing concert, and what is needed is a disciplinarian to instruct us concerning the leading motives, to seek the familiar law in the revealed wonders of the present time.

Aber im stillen Gemach entwirft bedeutende Zirkel

—SCHILLER.

The Passing of the Fijian.—The *British Medical Journal* states that the total population of the Fiji Islands is 121,773, according to the Colonial Office report, an increase of about 2,000 on the numbers of the last census in March, 1901. Of these, the pure-blood Fijians number 90,063, from which it appears that there has been the lamentable decrease in this short period of three years and a half of no less than 4,334. Most of this was due to a severe epidemic of measles in 1903, in which year the natives decreased by 2,481. In 1901 the decrease was 840, and it would seem as if the native race has been slowly but steadily disappearing ever since the terrible epidemic of measles in 1875, when over 40,000 are believed to have perished. The native death rate was 48.90 per mille last year, as against a white death rate of 15.25, and this with no epidemics and with a birth rate of nearly 40. The report does not comment on this high mortality which has been so long existent, but something might surely be done to ameliorate such conditions, though "native superstition and obstinacy" are represented as militating considerably against the measures lately taken to stamp out yaws.

CHORIONEPITHELIOMATOUS PROLIFERATIONS IN TERATOMATA,

ESPECIALLY IN THOSE OF THE TESTICLE; WITH THREE NEW CASES.*

ROBERT T. FRANK, A.M., M.D.
NEW YORK.

I. INTRODUCTION.

1. GENERAL REMARKS.

In recent years a peculiar form of tumor, known as chorionepithelioma, has been noted in connection with pregnancy. Since attention has been directed to this growth the reported cases have rapidly multiplied, so that they no longer should be regarded as a pathologic curiosity, but rather as a dangerous neoplasm with which the clinician may be confronted at any time, and which may convert, without warning, an apparently normal pregnancy into a rapidly fatal illness.

Hardly had these tumors become generally known, when renewed and added interest was aroused by the discovery of similar tumors in teratomata of the testicle. The resemblance of these two varieties of growths, though occurring under such diametrically opposite conditions, was too striking long to escape notice. It has been the effort of numerous workers to prove the kinship of chorionepitheliomata connected with pregnancy with those of teratomata.

In order to make clear the fundamental facts known about chorionepitheliomata it will be necessary to define these neoplasms, and the terms employed in describing them, although a more detailed account will be given later.

The chorionic villus, in normal pregnancy, is covered by a double layer of epithelium, of which the basal layer, variously known as the Langhans' cells (from their discoverer) or *Zellschicht* consists of clear polyhedral, mononuclear cells, containing glycogen. The covering layer is composed of larger protoplasmic complexes, giving on section the impression of polynuclear darkly staining sheets. They are known as syncytium. In the uterine musculature certain transitional types, called for convenience sake chorionic wandering cells, are found. In staining properties and general appearance they resemble the syncytium, but in size they are intermediate between the syncytial type and the *zellschicht*.

These three types of cells, all of fetal derivation, are regularly met with in the normal villous covering of the embryo and collectively may be termed the trophoblast. In the female, malignant tumors, directly continuous with the chorionic villi (often these villi are diseased, hydatid mole) and composed of the three types of cells just described, are known as chorionepitheliomata of pregnancy (Marchand). This chorionepitheliomatous or trophoblastic tissue was considered a distinct variety of tissue, peculiar to pregnancy, just as special as epidermis for instance. When, however, morphologically similar growths were found, quite independent of pregnancy, (in the ovaries of virgins and still more frequently in the testicle) this conception received a rude shock. The teachings of Marchand appeared discredited and, in fact, the so-called English Chorionepithelioma Commission was induced to hand in an opinion declaring that the tumors

* From the Department of Pathology of the College of Physicians and Surgeons, Columbia University.

in question should be classed as decidual sarcomata, as they had been regarded until 1895.

When the derivation of chorionepitheliomatous tumors of pregnancy, however, is compared with that of morphologically similar tumors found in the testicle or elsewhere, a similar derivation can be demonstrated. For the chorionepitheliomata of the testicle were, in most instances, an integral part of a teratoma, and the genesis of teratomata, as will be shown later on, is comparable in many ways with the processes of gestation.

With these preliminary considerations disposed of, the reader is ready to study the series of cases, and the theoretical deductions based on them which led Marchand and others to the interpretations now commonly held.

CHORIONEPITHELIOMA IN THE FEMALE.

Early Cases and Their Interpretation as Sarcomata.—R. Maier^{1*} and Sänger² are credited with the recognition of chorionepithelioma as a new and distinct variety of tumor. Maier regarded his two cases as a disease of the decidua of pregnancy. Sänger and Chiari-Pfeiffer³ independently described their cases as malignant metastasising sarcomata of the decidua, without according any share to either epithelial or glandular constituents. Before these authors had called attention to this new field, such tumors probably were classified among the carcinomata or sarcomata of the uterus, as are the three cases of Chiari⁴ published in 1877.

Marchand⁵ was the first to champion the epithelial nature of chorionepithelioma (unless we except the cases just mentioned, in which the tumors were mistakenly grouped with ordinary carcinoma of the uterus). In his first article he considered the syncytium of maternal origin, and was inclined to regard the simultaneous participation of the fetal ectoderm (the Langhans' cells), with the maternal syncytium as a symbiotic growth. Since then⁶ he has leaned more strongly toward the genetic unity of these forms, at first according the possibility of both a maternal as well as a fetal syncytium, and in a still later article,⁷ in 1903, going so far as to state that Langhans' cells and syncytium are not only of similar origin but are interchangeably capable of assuming either the one form or the other in response to different functional requirements. R. Spuler⁸ had arrived at similar conclusions as to the genetic identity of the two layers in a rather unconvincing study based on the morphologic similarity and transition forms seen in the covering of two hydatid moles; this work has received the support of C. Ruge.⁹

The Relation of Chorionepithelioma and Hydatid Mole.—An intimate but not clearly understood connection between chorionepithelioma, hydatid mole, pregnancy and abortion will be noted in the cases to be described, but at the outset this connection was not correctly interpreted. Especially intimate was the relation to hydatid. According to the statistics of Teacher,¹⁰ based on 188 cases of chorionepithelioma, 74, which is 39 per cent., were known to have had a preceding hydatid. In how many instances the mole was discharged unnoticed can never be determined.

The intimate relationship to hydatid naturally led to renewed study of this growth, and to a change of previously accepted views. Virchow's¹¹ dictum, which classified hydatids as a myxoma of the placenta in which the stroma played the active rôle, was finally dis-

carded, and again it is Marchand's views¹² which have been fully accepted. Accordingly, the stroma has been relegated to a secondary place, the swollen, translucent appearance being ascribed to hydropic changes. The active rôle is assumed solely by the chorionepithelium, both layers proliferating with undetermined and variable intensity. As observations increased in number, hydatid moles were found, in rare instances, to develop malignant and destructive qualities causing death from metastases (Salowij-Krzykowski¹³); others produced metastases but showed no really malignant properties, the patients recovering without radical operative measures (cases of Pick,¹⁴ Schlagenhafer, Case 1¹⁵).

Morphologic Criteria of Malignancy.—In view of the great practical importance of determining the malignant or benign properties of such growths as soon as observed, numerous authors have searched for some morphologic criteria on which definite prognostic value could be based. Neumann¹⁶ regarded the large syncytial cells, occasionally seen in the stroma or just beneath the epithelium, as signs of malignancy, but Pick, Ruge and others have discredited his work. Various other characteristics, such as the increased size and richness in chromatin of the nuclei of the syncytium (Gottschalk¹⁷), or the presence of numerous chorionic wandering cells (Ruge¹⁸), have not stood the test of time, for similar pictures were shown to exist in normal pregnancy (Marchand, Pels-Leusden¹⁹). All recent writers agree that the morphologic pictures of malignant and non-malignant chorionepithelioma are identical, and that the subsequent course alone can determine the outcome.

This question has again been reopened by von Velits,²⁰ who not only claims to be able to distinguish spontaneous regression by the microscope, but also sees regressive changes macroscopically! The diminished vitality of the Langhans' cells is supposed to show itself by the absence or lessened number of mitoses; the presence of chorionic wandering cells is taken to be an additional indication of degenerative changes. Hörmann²¹ discusses these assumptions of von Velits fully, and convinces the reader that these, like the previously mentioned findings of Neumann and Gottschalk, deserve to be discarded.

In destructive hydatids within the uterus, no difficulty was experienced in showing direct continuity between the chorionectoderm and the advancing tumor cells (Neumann, Gebhard²²). In metastatic growths, Pick¹⁴ first demonstrated this continuity in a vaginal metastasis of an otherwise benign hydatid; Apfelstedt and Aschoff²³ in a true chorionepithelioma. Veit²⁴ subsequently published his views on villous emboli in pregnancy, which promised to complete the link in the chain of evidence prepared by the findings of Pick, Apfelstedt and Aschoff. Recently, however, Schmorl²⁵ has cast a doubt on Veit's conclusions, by observing that only after long and protracted labor, in which much manual trauma has been sustained, do entire villi enter the circulation. In hydatids or eclampsia, if emboli do occur, cells and not villi are transported. This again emphasizes the fact that the cells and not the stroma are the active agents.

Ectopic Chorionepithelioma.—Schmorl²⁶ reported a case in which, after the complete expulsion of an hydatid, chorionepitheliomatous metastases developed throughout the body, the uterus and tubes, however, showing no changes. These cases, classified under the name of ectopic chorionepithelioma, have multiplied.

*The references to literature will be given at the end of the article next week.

until recently twenty-one were collected by Findley.²⁷ In many, a previously occurring hydatid, which was either operatively removed or spontaneously expelled, had been noted; in a few a supposedly normal pregnancy or abortion, without observed mole formation, was regarded as the etiologic factor. This would oblige us to assume that the normal fetal placental tissues can be the precursors of such malignant growths. Against such a doctrine Schmorl's work and the so frequently observed preceding placental degeneration bear strong weight. Instances of only partial hydatid change, insufficient to destroy the fetus, or twin pregnancy in which one of the children is normal, the other reduced to an hydatid rest, have been reported (see Marchand). The chorionic changes may be so small in extent as to escape notice, and therefore we should accept only with great reserve cases apparently arising from a completely normal placenta, unless this structure has been subjected to careful examination. As the malignant course develops only subsequently, such complete observation is usually not made.

Increase of the Lutein in Hydatid and Chorionepithelioma.—The discovery of an increase in the lutein of the ovary during the course of hydatid or chorionepitheliomatous growths, led to the conclusion that there might be a causative relationship. Some authors went so far as to consider this hyperplasia, which was found in the form of lutein cysts, as a direct stimulus to the chorion ectoderm, which then developed increased proliferative activity and malignant qualities. A contrary view is expressed by Seitz,²⁸ who, examining the ovaries of thirty-six women between the second and tenth months of gestation, found lutein cysts and a varying increase of lutein, in addition to that of the corpus luteum, in all but one case. Patellani²⁹ still more recently reopens the discussion by showing that in a large percentage of chorionepitheliomata the ovaries, in consequence of the lutein hyperplasia, assume a characteristic sausage shape, and undergo marked increase in size, sufficient to prove of diagnostic value. This phase of the question must as yet be considered unsettled.

The specific character of the growth is well illustrated by the decidual changes observed in chorionepithelioma away from the placental site, analogous to those seen in ectopic gestation (Schmorl, Risel,³⁰ Holzapfel³¹).

The Causes of Chorionepithelioma.—The opinions and theories advanced to account for the causation of chorionepithelioma are almost as varied and numerous as those entertained about the etiology of tumors in general, and may prove a valuable argument against a parasitic origin of carcinoma (Ribbert,³² Pick³³). Marchand believes nutritional changes and chemotactic influences at fault, and that the earlier in the course of a pregnancy such abnormal growth begins the more malignant the subsequent course will prove, though originally³⁴ he inclined to Ribbert's opinion, that a loosening of cells from the general complex afforded the starting point. Veit³⁵ still regards the maternal uterine tissues as the starting point of the growth, which, according to this author, begins before pregnancy. A somewhat modified view is held by Pfannenstiel,³⁶ who turns to the endothelium of the maternal decidua for the origin of the tumor.

Death of the fetus, softening of the uterine wall, etc., have all been assigned as possible causes. Schmorl declares, however—and his work is based on weighty arguments—that most likely in every instance a diseased placenta, probably hydatid, has preceded. Of the 158

cases he examined for emboli he found proliferation of the cell emboli in one eclamptic only, who died ten days postpartum. As he has seen similar syncytial changes in inflammations, he is inclined to disregard this case. Of the other cases the emboli were numerous in three cases of hydatid, and in three cases of abortion in which neither uterus nor ovaries had been subjected to examination. In some of these cases the cells appeared to be undergoing active proliferation, giving the picture of an early metastasis of an atypical chorionepithelioma. These observations, however, bring us no nearer the real primary cause of chorionepithelioma than before.

Experimental Work.—Little experimental work has been performed. The placental emboli of Lengemann,³⁷ Lubarsch³⁸ and Maximow³⁹ have shed no light on the subject. Aichel,⁴⁰ in dogs, obtained structures similar to hydatids by subjecting parts of the placenta to pressure. Such resemblance appears incomplete, and no observations as to the final outcome of these artificially produced hydatids are on record. Vassmer⁴¹ implanted portions of a chorionepithelioma into the peritoneum of rabbits without result. Birch-Hirschfeld and Gartner⁴² were equally unsuccessful with placental tissue introduced into the jugulars of two goats.

For further and fuller accounts of chorionepithelioma of pregnancy the reader is referred to Marchand, Risel, Teacher and Findley.

CHORIONEPITHELIOMA IN TERATOMATA OF THE FEMALE. RECORDED CASES.

Thus far I have dealt solely with those chorionectodermic tumors which showed a distinct relation to pregnancy. Similar tumors have been observed, however, in patients in whom pregnancy could be positively excluded, either through youth or sex. As chorionepitheliomata of the testicle will be discussed in detail later on, only such as have been observed in females will be treated of here. If the case of so-called hydatid mole in a virgin of 12½ years, passed at her fourth menstruation (Bock⁴³), were to be regarded as authentic, it would furnish an example of an hydatid on a congenital basis, but as neither the macroscopic or microscopic description is complete or convincing, this case must be discarded entirely.

Lubarsch⁴⁴ describes a large retroperitoneal tumor in a girl of 13. The case is incomplete, as the material was obtained at operation and the patient returned to her distant home, no autopsy being permitted. The tumor showed all the characteristics of a chorionepithelioma and we must ascribe its origin to a teratoma of the ovary, unless we accept Risel's view that in spite of the tender years of the patient a pregnancy can not be excluded. Lubarsch himself was inclined to consider the resemblance a result of metaplasia forming a *Doppelgänger* of this type of tumor.

Pick's⁴⁵ case of Hedwig R., in which chorionepithelioma was found in a teratoma of the ovary of a child 9 years of age, can not be subjected to a similar imputation. Here the chorionepithelium was in spots in direct continuity with neuroepithelium. In some regions the growth assumed more nearly the typical form of Marchand. Other ectodermal, in addition to mesodermal and endodermal constituents, were also found.

Michel⁴⁶ reports an analogous case of "carcinoma" of the ovary, which he offers in support of the non-specific value of such chorionepitheliomatous tumors, but far from agreeing with him, I consider that Pick⁴⁷ proves that this tumor is of similar origin as his own case of Hedwig R.⁴⁵

In order to grasp fully the significance of chorion-epithelioma in teratomata and to account for their occurrence in connection with these growths, it will be necessary to take a rapid survey of our present views on teratomatous tumors.

THEORETICAL CONSIDERATIONS; AND EMBRYOLOGIC SIGNIFICANCE OF TERATOMATA.

Wilms,⁴⁸ in his earlier works believed that true teratomata could be found in the ovary and testicle alone, because he derived them from a *Geschlechteszelle* and considered dermoids elsewhere in the body as genetically distinct. Bonnet⁴⁹ regarded the frequent occurrence of teratomata in the male and female generative glands as due to the comparatively large size of the urogenital anlage in the fetus, which would account for the more frequent location of independent blastomeres in this region, but does not entirely preclude their occurrence elsewhere. Traina⁵⁰ ascribes it to the exceptionally favorable nutritional conditions which he experimentally determined in the ovary.

Numerous observations of teratomata at other sites, as in the abdomen (where some skeptic might still suspect a hidden connection with the generative glands), and in the thorax and head, are, however, on record. Ekehorn⁵¹ has collected no less than thirty-one cases of mediastinal dermoids. Many of these showed the three fetal layers once demanded as the sign manual of true teratomatous growths. A case of teratoma of the mediastinum with chorionepithelioma has been recorded by Ritchie and will be considered more fully later on. Dermoids and teratomata of the brain, bladder, coccygeal region and liver are also known. We can no longer accept Wilms' first view, which placed the embryos or teratomata of the ovary or testis in a distinct and separate class. The Marchand-Bonnet theory,⁵² which accords a genetic equality to all composite dermoids, embryos and parasites, is now agreed to by nearly all. Derivation from a blastomere or impregnated pole cell, which at an early stage has been cast out of the complex, will account for the three eubryonal layers found in these growths. The earlier the liberation takes place, the more fetus-like and complex will be the resulting growth. Bonnet claims that an almost unbroken line can be traced from the acardiacus amorphus, on the one hand, to teratomata, in which the atypical proliferation has reached so high a degree that apparently simple tumors result. That not all layers need reach an equal degree of development is proved by the solitary tooth found isolated in ovarian stroma (Saxer⁵³), and interpreted as an unequally developed teratoma; or the struma colloides ovarii (Pick⁵⁴, Walther⁵⁵), in which one tissue had developed at the expense of the others, either hiding the other constituents, or completely replacing them. Whether we should regard the blastomere or pole cell as the origin of teratomata has never been decided. This point will be touched on later.

The cases of chorionepithelioma occurring in teratomata of the testis are widely scattered in monographic literature, although Risel has collected them to the year 1903. I will therefore briefly present all the available cases, but limit myself to their salient features.

2. CHORIONEPITHELIOMATA OF THE TESTICLE.

Nineteen cases of chorionepitheliomata of the testicle have been recorded. Some of these were at first regarded as sarcomata, and have only subsequently been reclassified under this new head. A detailed description of the clinical and morphologic characteristics of these tumors will be found in succeeding sections; in this sec-

tion the main features of the cases, and such deviations as will prove of special importance in the further discussion, or of special historical interest, alone will be considered.

In all the following cases (with the possible exception of Boestrom's) a primary testicle tumor was noted; and, in all which did not escape subsequent observation, death from metastases occurred within a comparatively short time. Microscopically, the chorionepitheliomatous portions will be found classified as either typical or atypical (see Section V), unless described in detail.

Three French reports, those of Malassez and Monod,⁵⁶ Carnot and Marie,⁵⁷ and Ch. Dopfer,⁵⁸ may be grouped together. These authors regarded their cases as sarcoma *angioplastique*, in which tumors, the large syncytial complexes, composed of darkly staining, vacuolated protoplasmic masses with many nuclei, attracted their chief interest. Because of the intimate relationship of the syncytia to the smaller blood vessels, and to extravascular collections of red blood cells, these authors ascribed vaso-formative properties, such as Ranvier had noted in the *taches laiteuses* of the rabbit's omentum, to the syncytium. Malassez recorded only the giant cell structures, but the others also describe clear, polygonal, uninuclear cells in carcinomatous, or alveolar sarcomatous arrangement. None of them either found or looked for teratomatous constituents.

Wlassow⁵⁹ added four cases to the literature. The data are incomplete. The major portion of each tumor was composed of clear, polygonal, glycogenic cells (of the Langhans type), arranged as in scirrhus or medullary carcinoma, or alveolar sarcoma. Syncytium was well represented in all. The metastases in Case 1 were typical. Noteworthy is the fact that the syncytium in the splenic metastasis showed a ciliary margin. Cases 3 and 4 contained teratoid portions, in the primary tumors, represented by ectodermal and mesodermal structures (cysts lined with various epithelia, embryonal muscle, cartilage, etc.). Because no endoderm could be found, Wlassow refused to accord an embryonal derivation to these tumors, and though he recognized their resemblance to the chorionepitheliomata of the female he, likewise, disregarded this feature. According to Wlassow the syncytium has a vaso-destructive, not a vaso-formative, function. The classification he adopted was that of a carcinoma *sui generis*, because an actively proliferating mesodermal anlage acted as the connective tissue of the growth. He chose the name of *epithelioma syncymatodes testiculi*.

Schlagenhauser⁶⁰ gave the first clear expression of the views now generally entertained. He claimed that the tumors in question are developed from teratoma, and are genetically equivalent to the chorionepitheliomata of the female. Going one step further, he assumed that rudimentary fetal membranes, in the teratoma, furnished the actual starting point for the tumor, and as evidence of the probability of a direct chorionic genesis, he cited cases of hydatid-like intravascular growths, discussion of which will be taken up later. The case he reported showed no distinctive features.

Schmorl⁶¹ published two cases. The first was described in greater detail by Steinert;⁶² the second was typical, showing both teratomatous and chorionepitheliomatous structures (the latter very limited in extent).

Boestrom's⁶³ case is noteworthy in that a small brain tumor, operatively removed, proved to be typical chorionepithelioma. Metastases in other parts of the body were of similar constitution, while the testicles were normal (?).

The case published by Steinert⁶² is of great theoretical importance, because not only were teratomatous (organoid) structures and chorionepitheliomatous tissues found in the testicle, but also in the metastases present in the retroperitoneal and mediastinal glands, and in the liver.

Steinert proposed three hypotheses to account for the teratomatous metastases: 1, Multiple blastomeres primarily deposited in the organs during early fetal life; 2, numerous blastomeres, in the primary tumor, which later were transported to other regions; 3, undifferentiated cells transported from the primary growth, at so early a stage of their development that they were still capable of producing all three fetal layers. Of these hypotheses the last is most plausible. The first presupposes multiple anlagen with a synchronous development of malignancy at their widely scattered sites; the second requires the assumption of quiescent blastomeres, hidden amid the tumor cells, while the third most nearly approaches our preconceived and more generally accepted ideas of tumor development (Ribbert). In the metastases, the chorionectoderm, in distinction to the other tissues of the teratoma, alone evinces "malignant" properties.

Steinhaus⁶⁴ case deserves no special notice. Teratomatous and chorionepitheliomatous formations both were in evidence.

Risel⁵⁰ (p. 145) reported two cases, which show important findings.

The first, in addition to the usual teratomatous and chorionepitheliomatous portions, contains ringlike forms resembling medullary canals of neuroepithelium, which, in one spot, are directly connected and continuous with syncytial masses, and where lining cysts, show complete transitions from ciliated to cubical, or even epidermoid epithelium.

The chief conclusions drawn from this case by Risel are that two forms of embryonal epithelium are here encountered in active proliferation—the chorion epithelium, with all its characteristics, and neuroepithelium, which shows a tendency to form analogues of a medullary tube; secondly, that the transition of cells of chorionepitheliomatous appearance with other epithelial cells, amid other tissues, bears witness to their genetic unity and speaks against their derivation from a special anlage of fetal membranes. He regards them as a special form of the fetal ectoderm, which in this instance has also produced actively proliferating neuroepithelium.

These conclusions agree with those entertained by L. Pick and appear to be fully warranted. Pick has most convincingly demonstrated direct continuity between neuroepithelium and chorionepitheliomatous cells, in his case of ovarian teratoma.

The second case of Risel (p. 151) is incomplete because the primary tumor is lacking. The metastases, with the exception of the prevertebral are typical. In the prevertebral tumor are portions composed of smaller, darker, uninucleated cells, often in ductlike or alveolar arrangement and without the accompanying fibrin and necroses, typical of chorionepithelioma.

According to Risel these areas are derived either from a proliferation of the epithelium of the seminiferous tubules, of the primary growth; or, as is more probable, from some epithelial tissues contained in the primary testicle teratoma (which was not available for examination).

Emanuel⁶⁵ reported a case whose distinctive features resembled those more fully discussed in connection with

the case of Askanazy.⁶⁶ The metastases were typical. The primary growth contained teratomatous formations and chorionepitheliomatous tissue which, in some parts, imitated carcinomatous, in others, papillary configurations.

von Hanseemann's case⁶⁷ lacked the primary testicle tumor, which had been previously removed. Noteworthy are the metastases in the aortic glands; in these cysts, with sero-sanguinolent contents lined with cubical and cylindrical epithelium, pointed to the teratoid nature of the primary growth. (These cysts, according to v. Hanseemann, in no way resemble the so-called "lymphatic cysts" sometimes found in the lymph glands.) The metastases elsewhere were typical. For the interpretation of these findings, what has been said in connection with Steinert's case applies.

Askanazy⁶⁶ reported the case sent to Dr. L. Pick by Dr. Salén of Stockholm. Its importance lies chiefly in the systematic study of the various forms assumed by the Langhans cells. Although some portions of the primary tumor are quite typical, transitions, not only to alveolar arrangement of the Langhans cells, but also to duct-like and complex papillary forms, clothing cyst walls, are described. Askanazy concludes that besides the usual typical and atypical types of Marchand the Langhans cells may assume alveolar sarcomatous, carcinomatous, cystomatous, angiomatous or papilliferous forms. Isolated occurrence of this type of cell in teratomata of the ovary and testicle, simulating simple tumors (epithelioma chorionectodermale in the sense of Pick) can thus be accounted for by an excessive growth of these elements. The chorionepitheliomatous tissue, according to this author, can be identified by its numerous characteristics even when it assumes fantastic or complicated shapes, and moreover, can be directly and unbrokenly traced to simpler forms which correspond to the types laid down by Marchand, and among other constituents contain syncytium, showing a foamy appearance, ciliated margin and a tendency to fibrous transformation.

Scott and Longcope⁶⁸ are the only American authors who reported a case of chorionepithelioma in the male. The testicle was undescended, and contained no teratomatous tissue (only cells of the Langhans type); the metastases were typical.

The last case to be mentioned is that of H. Dillman.⁶⁹ The testicle contained teratomatous, "adenocarcinomatous" and chorionepitheliomatous structures. The latter were represented only in one very minute area.

A case described by Langhans⁷⁰ appears so questionable that I have not included it in the literature. A description of this case, and the metastases of a testicle tumor examined by Eden,⁷¹ which almost positively was a chorionepithelioma, will be found in Risel.⁵⁰ Eden's case is too incomplete to be of real value. Historically it is of interest because it influenced the English commission to form a judgment against the fetal origin of chorionepithelioma in the female.

THE AUTHOR'S THREE CASES.

To these nineteen cases collected from the literature I am able to add three additional cases. The first two are from material kindly placed at my disposal by Prof. F. C. Wood, from the collection of St. Luke's Hospital. The first case was operatively removed seven years ago. At the time, the tumor was classified as a sarcoma of the testis. The second was very recently removed, and given to me by Professor Wood with the diagnosis of chorionepithelioma of the testis. The third case is derived from

a tumor of the mediastinum in a patient from the Roosevelt Hospital.

In all these cases the material had been put up in formalin or very weak alcohol, and in no instance was it possible to demonstrate glycogen. Sections were cut by the celloidin method. Besides the routine hematoxylin-cosin staining, picro-acidfuchsin and iron hematoxylin were employed.

CASE 1.—C. P. W., St. Luke's Hospital, operated on Nov. 23, 1897.

History.—The patient was a man 40 years of age. For two years enlargement of one testicle had been noted, the increase being gradual and uniform. Local applications and tapping, at which only a little bloody fluid was withdrawn, proved of no service, but injection of iodin was followed by a marked reduction in size. During the past few months the tumor has again, and more rapidly, increased, and the patient has lost twenty pounds in weight. The tumor was removed. The subsequent history is unknown.

Macroscopic Examination.—The testicle and epididymis are completely fused, forming a mass irregularly quadrilateral in shape, 10 cm. by 10 cm., and 6 to 8 cm. thick. The surface is smooth, with dilated blood vessels showing through the tunica and occasional slight nodular projections. At the upper pole a thick but otherwise normal spermatic cord is found. Its veins are varicose. The color of the entire tumor is a faded greenish-blue from the preservative, in which it has lain for seven years. Sections across the entire growth show several large districts separated by dense, coarse, fibrous septa which converge upward and toward the beginnings of the cord. The largest and most central area has an irregular pitted surface and brownish-gray uniform color. Nearer the cord the tissues are denser, more fibrous, and smooth on the cut surface. At the lower pole the color is more yellowish and mottled yellowish-brown. In almost direct continuity with this portion of the mass is a region of diffuse hemorrhagic appearance which has all the characteristics of the often described "recent thrombotic areas" (Hansemann and others). Small punctate hemorrhages are seen everywhere in this neighborhood. Nowhere are there any indications of cystic structures, bone or cartilage. No testicle substance could be found. Numerous pieces were removed from all parts of the tumor, which was too large for making serial sections.

Microscopic Examination.—The findings are very varied, but certain types of cells in different groupings can be isolated on analysis. The albuginea is normal except for occasional areas of fibrous thickening. From this tunica septa extend into the tumor; the larger strands were already visible macroscopically. By frequent subdivision the strands become thinner and thinner until narrow fibrous bands surround the alveolar portions of the tumor epithelium. No Leydig's cells are seen in the testicle proper; at the beginning of the spermatic cord, which is normal, many of these cells can be observed. The vas is normal. No seminiferous tubules were found.

The macroscopically necrotic areas are formed by a structureless faintly granular mass traversed by bands of fibrin, and occasional areas of degenerating round cells. At the margins of these large areas poorly staining cells of various kinds occur, some well advanced in a degenerative process, others still showing traces of nuclei and cell outline. There are no large or diffuse hemorrhagic areas, but small extra vascular collections of red blood cells are not uncommon. Except in the old fibrous septa no blood vessels of any size appear. Between the tumor alveoli, soon to be described, occasional capillary vessels may be seen, some of which show a more intimate connection with the tumor cells.

1. The epithelial cells are polyhedral, with cytoplasm in spots taking a fairly intense eosin stain, especially in the most actively growing portions, in other parts very light or finely granular and transparent. The cell outline is remarkably sharp and shows the effect of contact pressure. The nuclei are round or oval, have a sharp nuclear membrane, deeply staining chromatin and one or two nucleoli. The size of the cells varies from 10 to 14 microns, that of the nuclei from 8 to

11 microns. The line of demarcation between the fibrous stroma and the tumor cells is very sharp. At the edges of the tumor the advancing cells appear in longer narrow columns, and here and there a few may be seen in the narrow tissue spaces.

2. In some of the alveoli are scattered larger and more deeply staining cells of varied shape, with multiple nuclei. They resemble foreign body giant cells. In other districts enormous protoplasmic masses, reaching 500 to 700 microns in length, and 50 to 100 microns in width, and with very numerous nuclei, are found at the edges of the alveoli, also sending processes between the cells of type 1. These syncytial forms may have a homogeneous, deeply staining protoplasm, but more often a vacuolated and "foamy" appearance predominates. The nuclei vary in size, but on the whole are smaller than those of the main tumor cells, more deeply staining, and with a closer nuclear network. Usually no nucleoli can be distinguished; no mitoses were seen. Fragmentation, pyknosis, vacuolation, and other degenerative nuclear changes are not uncommon. Occasionally giant nuclei of the most bizarre shapes can be found. Where the foamy or vacuolated cytoplasm is present the nuclei show semilunar or other compression or distortion shapes. Within the syncytium or at its edges are cells of type 1, some well preserved, others degenerating, still others showing a nearer approach to the syncytial type by deeper staining of the cytoplasm and indefinite cell outline (Fig. 1).

3. Sometimes arising from the spreading syncytium, at others independent of it, are narrow, elongated cells reaching a length of 20 to 30 microns with most intensely staining elongated nuclei. These cells may be seen within the alveoli, and also advance into the surrounding fibrous tissue. Wherever they are found the cell growth is very active.

4. Transitional cells of very varied size and appearance are seen arranged like the cells in epithelioma of the skin. The alveoli usually show a rounded outline, and almost invariably contain large and numerous syncytial masses. The cells may be but little larger than cells of type 1; others reach three or four times their dimensions and resemble large and irregular cartilage cells. Their protoplasm is uniformly light, their cell outline sharp. Many are found within the syncytium, their outlines being well preserved. The nuclei are light, show much chromatin, nucleoli and a well-marked nuclear membrane. The most diverse sizes and shapes are encountered. Mitoses are rare, but not entirely wanting (Figs. 2 and 3).

The different quantitative arrangement of these constituents gives an extremely varied picture. The syncytial masses usually have large collections of red blood cells in close proximity; some of the blood cells are also found in the vacuoles of the syncytium, which often acts as a boundary to large blood lacunae. Capillaries are also seen surrounded by cells of type 1, and may end in the blood lakes just referred to. Their endothelium may be preserved, or only partially destroyed, syncytium or cells of the other types forming the boundary.

No glycogen could be demonstrated in the specimen, which had been preserved for seven years in formalin, later in weak alcohol, but the cells of type 1 morphologically were similar to cells containing glycogen.

To sum up, the tumor was composed of an alveolar epithelial growth which showed a tendency to hemorrhages and necrosis. The tumor elements consisted of cells closely resembling Langhans' cells, syncytium, chorionic wandering cells and transitional forms, arranged in some spots as in the typical form of Marchand, but yet in the main the alveolar arrangement predominating. Single fields can be found in which no one could distinguish the picture from that of a chorion-epithelioma of the female. This effect is heightened, where, by chance, a projection of the stroma forms a villous-like figure covered with Langhans' cells and syncytium.

No other ectodermic, no mesodermic or entodermic structures were found.

CASE 2.—R. C., St. Luke's Hospital, admitted March 10, 1905, aged 16 years.

History.—The family and previous history of the patient is negative. Two months ago he noticed that the left testicle was larger than the right one, and it has gradually increased until now it has attained the size of an orange. Until one week ago there was neither pain nor discomfort, but since then the tumor is tender on palpation. For the last two nights a dull testicular pain has prevented sleep. There was no loss of flesh and strength, and no other symptoms.

On examination nothing but the swelling of the testicle was found.

The testicle was removed; the wound healed promptly. The subsequent course will be followed, if possible.

Macroscopic Examination.—The testis and epididymis form a single mass about the size of a goose egg. The tunica is smooth and normal; the cord shows no macroscopic changes. On sections the diffuse hemorrhagic appearance is striking. The hemorrhages have not the "thrombotic" form usually noted, but a more arterial, brighter red, and less even carnified consistence. Large areas show a low papilliform surface such as is seen in recent adherent pericardium. Macroscopically no cysts are noticeable. Here and there the hemorrhages are more compact and typical.

The growth had already been cut into several pieces when it reached me. Numerous blocks were prepared and examined.

Microscopic Examination.—Large areas of fairly normal testicular tissue were found. Some seminiferous tubules appear to be functioning; others, nearer the tumor, are undergoing pressure atrophy, and still others are almost unrecognizable and necrotic where embedded in a granular homogeneous mass. In some spots the active tumor tissue is in fairly close proximity to the tubules, but always separated by a considerable layer of fibrous tissue. Nowhere do the seminiferous tubules show an increased proliferative activity or break through into the surrounding stroma. The stroma and Leydig's cells are considerably and uniformly increased.

The tumor proper is separated from the remaining testicular substance by no distinct capsule, but yet there is everywhere at least some intervening space filled by fibrous or myxomatous tissue.

The teratomatous nature of the growth is unmistakable. The ectoderm is most typically represented by rudimentary skin in one spot. Here both the stratified stratum corneum and the deeper rete Malpighii are plainly shown lining one side of an oblong cavity about 8 mm. long, and shading off into a lower multiple layer of epithelium, which finally becomes cubical and single, dipping down to form two simple glandlike structures and eventually breaking up and diffusely invading the stroma. By means of serial sections a direct connection between the epidermis and the typical papilliferous structures now to be described could be traced, the transition being gradual but unbroken (Fig. 4).

Numerous simple cysts, as well as papilliferous cysts, are lined with epithelium. These epithelial cells are cubical or of irregular polyhedral shape, with sharp angular cell outline and clear cytoplasm. The nuclei are large and oval, have a distinct cell membrane, often one or two nucleoli, and granular chromatin network. Mitoses are common. The size of the cells is fairly uniform, varying between 10 and 14 microns, the nuclei reaching 8 to 12 microns. In many spots the structures are very complex, cysts, true papille (shown to be such by serial sections), and rugae form a bewildering appearance almost similar to that seen in malignant adenoma. On the papille the epithelium is often multiple. In numerous places the epithelium invades the stroma, forming cell columns or quite as often assuming a diffuse reticulated distribution. In the neighborhood of hemorrhages or of small blood vessels, the epithelium leaves the main papille in an irregular fan-shaped form, the cytoplasm is darker, the nucleus larger, less regular, and the type changes to that of the chorionic wandering cells (Fig. 5). These cells have a nucleus, 10 to 15 microns or more in size, and the cell body may reach as high as 30 microns. These cells abound among the hemorrhagic detritus, and about, or even under, the endothelium of the small ves-

sels, which show incomplete or eroded walls. Among this type of cell numerous smaller and lighter cells similar to those previously described are scattered. No large syncytial masses were found in spite of repeated and thorough search. The epithelium, however, in many regions has a more syncytial appearance due to loss of cell boundaries. About some blood vessels of larger than capillary size, but with very thin walls, the epithelial cells of both types are grouped, so as to give the appearance of a perithelial sarcoma. The cells are closely placed about the vessel, but away from it gradually become further separated into alveolar forms by the connective tissue.

Circular or elongated tubes lined with a high, cylindrical epithelium with small basal nucleus or an occasional goblet cell are found. They have a distinct membrana propria, and one or two circular layers of unstratified muscle surround them. These structures were interpreted as entodermal formations.

The mesoderm is represented by fibrous, fibrosarcomatous and true myxomatous tissue, also by scattered unstriped muscle, and by several islets of cartilage.

Of the well preserved portions of the growth by far the greater part is composed of large irregular alveoli, very similar to the alveoli of carcinoma. The stroma has already been described. In some spots it sends fine fibrils into the alveolus, but on the whole any indication of intercellular substance is wanting.

This case must be interpreted as a teratoma containing all three layers, in which chorionectodermal tissues (in the sense of L. Pick) have undergone active proliferation. The Langhans cells line cysts, cover papillae, surround blood vessels, and assume more diffuse though never typical alveolar arrangement. Chorionic wandering cells are common; large syncytial formations are not represented. In one spot an unbroken connection between an epidermis-lined cyst and diffusely growing chorionectodermal tissue could be traced.

CASE 3.—N. S., male, aged 21, was admitted to Roosevelt Hospital Sept. 17, 1904; died Oct. 21, 1904.

History.—According to the patient's own account the present illness began three weeks previously with a chill followed by fever. For the last two weeks he has had cough and blood streaked expectoration, with sharp thoracic pain between the shoulder blades, most marked while lying down. There has also been weakness, dyspnea and loss of weight.

On admission the veins of the neck and shoulder of the left side were more dilated than on the right. The heart was displaced slightly downward and to the left. Above the heart was an area of dullness, and a loud systolic murmur could be heard posteriorly at the level of the sixth dorsal vertebra. Anteriorly over the left upper lobe was dullness, bronchial voice, diminished breathing and sibilant and sonorous rales. Similar signs were heard over the right lower lobe posteriorly. The abdomen was distended without the signs of free fluid. The temperature was irregular, hectic, and rose to 104 degrees. On September 29 the patient coughed up half an ounce of pure blood. He died with symptoms of general weakness and dyspnea. On admission the case was diagnosed as one of aortic aneurism; later the diagnosis was changed to that of mediastinal tumor.

An autopsy was performed, but no record kept. Small portions of the lung, liver and necrotic parts of the mediastinal mass were preserved. At no time was any note made of the size of the testicles; presumably they were of normal size.

Macroscopic Examination.—The material from this case consisted of numerous small pieces from the mediastinal mass and nodules from the lung and liver.

The mediastinal growth was of a dark green-brown mottled color, with circular hemorrhagic and necrotic areas of very friable consistency and smooth marble-like surface. The pieces from the lung showed fairly normal lung tissue, which was spongy and contained air. Within these pulmonary tissues irregularly spherical nodules from pea to cherry size were scattered. In color they corresponded to the hemorrhagic

Fig. 1.—Case 1. Tumor of the testicle. To the left is an enormous vacuolated sheet of syncytium. To the right and above is an alveolar collection of Langhans cells surrounded partly by syncytium, which is also found in the center of the alveolus, partly by a fibrous septum. Lower down the syncytium contains isolated Langhans cells, giant nuclei and vacuoles, within which are a few red blood cells.

Fig. 2. Case 1. Tumor of the testicle. Alveolar arrangement of Langhans cells, with intimate relation to large syncytial masses. The syncytium is typically vacuolated and bounds large blood spaces. Transition types abound. At the periphery (left upper corner) are fibrous septa and granular detritus.

areas seen in the mediastinal growth, but they were of firmer consistence and less necrotic.

The portions of the liver preserved were of uniform brownish color, and grossly showed no changes. Glisson's capsule appeared thickened. The nodules were similar in size, color and shape to those found in the lung, except in one spot where a larger and more diffuse area was found. This was less sharply demarcated from the surrounding liver tissue and showed advanced areas of necrosis centrally. In close proximity to this region were two nodules, one of pea size, the other nearly as large as a cherry, of totally different nature. Irregularly spherical but traversed by fibrous bands, these tumors were white in color and softer in consistency, showing on section a tendency to project above the surrounding liver. Here there were neither hemorrhages nor necrosis.

Microscopic Examination.—With the exception of the two small liver nodules just mentioned the eight nodules of liver and lung were exactly similar. Their outline was fairly sharp. Centrally, in each, was a large, hemorrhagic area composed of degenerating red blood cells, fibrin, detritus and almost unrecognizable cell material. Peripherally was a cellular area of varying width formed by clear polyhedral epithelial cells strongly similar to those of the Langhans type, with large and typical syncytial masses. The syncytium showed numerous well preserved nuclei, vacuolation and protoplasmic processes. Moderate numbers of transitional types were present. Large and small blood lacunae abounded near, or surrounded by, the syncytial masses. The arrangement was that of the typical chorioneplithelioma of Marchand. The surrounding lung tissue in some portions was normal; in others the alveoli were filled with a pneumonic exudate. In some regions a fibrous septum of considerable thickness, probably antedating the tumor, separated healthy and diseased areas. The liver tissues show much bile pigment in all the liver cells. Where the tumor and liver tissue about the difference in cell types is very distinct. The liver trabeculae are dark,

filled with pigment granules and have a homogeneous appearance. The Langhans cells stand out clear and lighter and show neither pigment granules nor dark coloring. The syncytium also is distinct; its nuclei larger and darker than that of the liver cells; its cytoplasm vacuolated

Fig. 3. Case 1. Tumor of the testicle. Syncytium and Langhans cells as in the typical chorioneplithelioma of Marchand; at the edges young connective tissue.

and more granular. Although in many places in direct contact, no continuity with liver tissue could be found. The liver cells often show the effect of pressure. There are marks of chronic congestion and Glisson's capsule is thickened. A few outlying vessels are filled with Langhans cells (Fig. 6).

The contrast between the pigmented liver cells and the clear, light tumor constituents is very striking.

The pieces from the mediastinal tumor show formless necrotic tissue.

As the testicles were not examined, and the parts of

Fig. 4.—Case 2. Teratoma of the testicle. Part of a narrow cavity 8 mm. long is shown. To the left is epidermis with horned epithelium, merging toward the right into a lower layer of epithelium, which dips down to form two glandlike structures. At the bottom of the deeper gland the epithelium is more darkly staining and fused. In direct continuity is a more alveolar arrangement of the cells, which by unbroken transitions merge into the papilliferous structures, composing the main part of the tumor. To the left and below is one of these papilliferous cavities.

The two whitish metastases are composed of a single type of cell somewhat smaller than those of the zellschicht, with clear though more deeply staining cytoplasm and similar nucleus. They are arranged like the cells of an alveolar sarcoma, the fibrous tissue entering and subdividing in the very large irregular alveoli. At the periphery the cells in small groups invade the liver substance, crowding aside the liver

the mediastinal tumor submitted to the microscope showed only necrosis, the genesis of this tumor can not be cleared up. Very possibly a more careful autopsy might have demonstrated a mediastinal dermoid or teratoma. The metastases are absolutely characteristic of chorionepithelioma.

(To be continued.)

Fig. 5.—Case 2. Teratoma of the testicle. Below, this shows a complex of Langhans cells on a fibrous stroma (infiltrated with round cells). Above the cells assume the type of chorionic wandering cells and approach a small arteriole (the red blood cells within this are drawn too small) whose wall they invade. At the extreme upper angle is necrotic material and debris.

Fig. 6.—Case 3. Liver metastasis. Typical chorionepithelioma. In the center an enormous blood lake bounded by Langhans cells and syncytium. The cells are compressed and contain bile pigment.

FRACTURES OF THE OLECRANON TREATED BY SUBCUTANEOUS EXARTICULAR WIRING.

JOHN B. MURPHY, A.M., M.D., LL.D.
Professor of Surgery, Rush Medical College.
CHICAGO.

Considering that coaptation of fragments in fractures of the olecranon is not easily obtained by manipulation, the maintenance of the fragments is frequently an impossibility, and the treatment by splints or casts is frequently followed by ankylosis or impairment of motion, I have come to the conclusion that operative treatment is the most advisable. On the other hand, the exposure of the elbow joint appears to me to be dangerous. The open treatment that Lord Lister applied to fractures of

History.—Patient, 40 years of age, a police officer, was caught between a wall of an alley and a wagon by a runaway team, May 22, 1905. His right arm was slightly bruised and the right elbow severely hurt. Suffering great pain, he consulted a physician shortly after the accident. Physician put the limb in flexion (about 90 degrees), and applied a plaster-of-paris cast to the elbow, stating that in all probability patient's elbow would remain stiff. For thirty hours after the accident patient had considerable pain.

Examination. He came to my office on the request of his physician May 23. In accordance with an understanding with his first physician, I removed the cast and examined the arm with the fluoroscope. I found a transverse linear fracture of the olecranon. The olecranon was divided into two halves, which were separated by a distance of three-fourths of an inch. In my opinion, an operation was advised and patient consented. The indication for operation in this case was the great separation of the fragments, the

Figs. 1 (lateral view) and 2 (posterior view).—Wiring the fragments of the olecranon together. *a*, Incision; *b*, twist or tie of wire; *c*, hole drilled in bone for passage of wire; *d*, fracture; *e*, passage of wire through tendon of triceps.

the patella, and which is practiced to a great extent today in England, does not appeal to me in the case of fractures of the olecranon. I have always feared to open a joint, even under the greatest aseptic precautions, for we all know that the liabilities of infections in a joint are greater than those in the peritoneum. Therefore, the subcutaneous and exarticular wiring of the olecranon seemed to me the most advisable and the simplest procedure. As far as I have been able to learn from the literature, subcutaneous wiring of the olecranon has not been resorted to by any one else. It is such a simple and practical procedure that I have felt that its publication might be beneficial to the general practitioner and surgeon, who undoubtedly have had unpleasant experiences with such fractures. The following is the history of our case:

upper fragment being drawn upward by contraction of the triceps. I was convinced that without operative treatment it would be very difficult to coapt the fragments and that a fibrous union would be the result.

Operation. May 24, 1905, a longitudinal incision 1.3 of an inch long was made on the external aspect of the ulna, one-half inch from its articular surface, and tissues were divided to the bone. A smaller incision was made on the corresponding inner side. I perforated the base of the olecranon with an eyelet drill, which ran transversely from outward inward. I threaded the drill with a fine aluminum-bronze wire, drawing it through this transverse canal (Fig. 2). The wire was carried upward under the skin on the inner surface of the elbow and then drawn out through another small incision, one-sixteenth of an inch, made at the level of the apex of the olecranon. The wire was then reinserted and directed transversely from inward outward, passing it through

the tendon of the triceps above the olecranon, and then drawn out to a corresponding outward point through a very small incision similar to that made on the inner side. The wire was again reinserted and pushed downward under the skin until it was finally brought out through the initial external incision. The circle once completed, traction was exerted on the wire until I was sure that the two fragments were in perfect coaptation, the latter being easily and satisfactorily accomplished. The ends of the wire were twisted several times and then divided by scissors close to the bone. By this procedure the skin was incised at four points (Fig. 2), the largest incision being $1\frac{3}{4}$ of an inch in length.

The coaptation of the fragments was perfectly assured by the traction of the wire. The latter could not slip, the lower part of the wire being inserted through a bony canal, while the upper part passed through the tendon of the triceps and pressed against the bony button of the olecranon (Fig. 1, E). The main advantage of this procedure is, first, that the operation is entirely extirpation, an advantage which, of course, needs no further explanation or praise; and second, passive motion can be instituted immediately after the wiring.

The operation finished, the elbow was put in extension and so maintained by an anterior plaster splint which was fastened by a bandage. Following the operation, the patient had slight pain, which in a few days diminished considerably and finally disappeared on the twelfth day, when patient left the hospital entirely free from pain. The splint was temporarily removed on the third day and each of the following days, passive motion being used, and at the end of four weeks entirely abandoned. The patient has since resumed his work and has had perfect use of his arm and no pain.

Postoperative History.—Patient was thoroughly re-examined Oct. 22, 1905. Form and contour of the right elbow similar to that of the left. The natural obtuse angle formed by the axis of the right arm and forearm is equal to that of the left. Flexion and extension of the right elbow is painless and equal in extent to that of the left elbow. Palpation reveals a perfectly smooth surface; in other words, there is no interruption in the continuity of the periosteum of the olecranon. No pain on active or passive motion. The right elbow joint is functionally normal. Where the wires were twisted the continual mechanical irritation produced a small bursa, which does not inconvenience the patient in the least.

I hope the general practitioner will realize that this procedure is both practical and harmless, and does not require great surgical skill for its performance; furthermore, it gives assurance of a perfect result.

A CASE OF INFANTILE SCURVY.

GEORGE DOCK, M.D.

Professor of Medicine in the University of Michigan.

ANN ARBOR, MICH.

Infantile scurvy is a comparatively rare disease everywhere, though becoming more frequent. Chiefly because of its infrequency it is often unrecognized, and so reports of single cases, even if they add nothing to the real knowledge of the subject, may be useful by calling attention to the existence of the disease when it might otherwise be overlooked. For this reason I report the first case that has been treated in the university hospital.

Summary. Case of infantile scurvy treated for two months with diagnoses of neuritis and probable anterior poliomyelitis, with sore mouth. Easily recognized as infantile scurvy by ocular proptosis with subcutaneous hemorrhages of the eyelids, characteristic swelling and discoloration of gums, depression of anterior thoracic wall, swelling and tenderness of wrists and ankles, slight rickets, sweating of head; rapid recovery on change of food and use of orange juice.

Patient. E. B., aged 10 months, admitted to university hospital Oct. 23, 1905. The mother, aged 24, was very small as

Fig. 1.—Dr. Dock's case of infantile scurvy. The photograph was taken after improvement began, and the front of the thorax does not look so much like that of a cadaver after necropsy as it did in the beginning.

Fig. 2.—Skiagraph showing swollen arm.

Fig. 3.—Skiagraph showing swollen leg and foot.

a baby, but has always been well since then. She looks well and is of robust frame. The father, a well-to-do farmer, is 26 years old and in good health. The patient, their first child, was born Dec. 26, 1904. The birth was not difficult.

History.—The mother tried to nurse the baby, but after three weeks was obliged to stop. Milk and water, equal parts, sterilized by boiling for one hour, was next used. Barley gruel and milk sugar were added to the milk from the third week. The child vomited curds and was tympanitic, so a change was made, at 5 weeks, to the following preparation: Milk, 10 tablespoonfuls; water, 24 tablespoonfuls; Mellin's food, 4 teaspoonfuls.

As this was not taken well, the Mellin's food was increased and the water lessened, and up to the time the patient came to the hospital she took the following: Milk, 25 tablespoonfuls, water, 7 tablespoonfuls; Mellin's food, 9 teaspoonfuls. The mixture was heated to 165 F. for about ten minutes. The quantity taken at each feeding was rarely more than 3 ounces, and for some time five feedings were given in twenty-four hours.

The weight at birth was 8½ pounds; at 5 months it was 14 pounds; at 8 months, 15½.

Constipation has been the rule, rarely interrupted for a day at a time with as many as three to six stools in a day. In the end of August there was bright red blood in the stools and then for from two to three weeks the stools were almost black, becoming natural only about October 10.

The lower central incisors were cut at six months, without special difficulty. At the end of August the upper central incisors began to appear. At that time it was observed that the baby screamed when her feet were touched. Soon she ceased to use her legs, but there were variations in the degree of this. Then the back became sensitive to touch and she stopped sitting up in the middle of September. Then the arms became quiet, the left almost entirely so. The right arm was only moved to put the thumb in the mouth, where it was kept most of the time. As the upper teeth were slow in coming through the gums were incised. About the last of August the upper gum became swollen, appearing like a blood blister which subsided slightly at times, though the main swelling never disappeared nor became much smaller. The lower gum became swollen after the upper one.

About October 15 the right upper eyelid swelled suddenly. Eye salve was applied. The swelling subsided, but left a bluish red discoloration. The left upper eyelid became swollen October 23, and when admitted the lid was swollen so it did not open, was deep pink and edematous looking. The head has perspired profusely for a long time. There has never been any sign of laryngismus stridulus.
